The general conclusion from this and the previous work is that a uniform type of life evidently tends to a fairly uniform excretion of tissue cells from the udder. Outside causes may temporarily increase this excretion, and high counts are not necessarily connected with any diseased or disordered condition of the mammary gland. When the cell count is high for any reason, the cells themselves are always well defined, showing little signs of degeneration, and also stain in a much more characteristic and definite manner, a fact which is difficult to explain if they are to be considered as blood elements.

Contributions to the question as to whether ingested copper is secreted in the milk, C. Titze and W. Wedemann (*Arb. K. Gsnahtsamt.*, 38 (1911), No. 1, pp. 125–136).—Solutions of copper sulphate and leaves on which copper mixtures had been sprayed were given to 2 milk goats. The milk was found to be free from copper except in two instances, where a slight trace was found. Copper and copper sulphate was constantly found present in the urine and excreta. Slaughter tests showed considerable copper in the liver and small amounts were present in the kidneys, blood, and heart, with traces in other organs. No trace of copper was found in the udder, muscles, or fatty tissues.

Scarlet fever in relation to cow's milk. W. Hunting (*Vet. Jour.*, 67 (1911), No. 431, pp. 259–263).—From a critical analysis of the evidence where milk-borne outbreaks of scarlet fever have been reported, the author concludes that none of the reported cases have as yet been proved to be of bovine origin, although it is probable that the disease may be carried by milk when contaminated through a human source.

Publicity and payment based on quality as factors in improving a city milk supply, H. A. Harding (*New York State Sta. Bul.*, 337, pp. 79–114, chart 1).—This records the result of a study of the influence upon the milk supply of Geneva, N. Y., of publicity regarding the sanitary conditions under which the milk was produced and of payment to the producer on the basis of the quality of the product.

The method employed was to score each dairy quarterly upon the basis of the sanitary conditions under which the milk was being produced, to furnish this score to the producer and retailer so that it could be made the basis of payment under their contracts, and to publish the score of all of the producers, with the names of their retailers, so that the consuming public could purchase intelligently. In comparing dairies conditions were reduced to a numerical basis by means of a score card, an outline of which is given. The dairies were classified under the following heads: Poor, where filthy conditions were present; medium, where conditions were merely dirty; good, where the conditions were fairly clean; and excellent, where they were both clean and sanitary.

"There is every reason for thinking that the sanitary conditions of this city supply at the beginning of this study were as good as the average of the cities
of the State. A careful initial inspection showed that 37.5 per cent of the dairies were ‘poor,’ 57.5 per cent ‘medium,’ and 5 per cent ‘good.’

“At the end of one year 2.9 per cent of the dairies ranked as ‘excellent,’ 58.9 per cent ‘good,’ and 38.2 per cent ‘medium.’

“At the end of the second year 8.6 per cent of the dairies ranked as ‘excellent,’ 82.8 per cent ‘good,’ and 8.6 per cent ‘medium.’

“At the end of the third year 12.8 per cent of the dairies ranked as ‘excellent,’ 74.4 per cent ‘good,’ and 12.8 per cent ‘medium.’

“At the end of the first quarter of the fourth year 12.8 per cent of the dairies ranked as ‘excellent’ and 87.2 per cent as ‘good,’ the ‘medium’ grade having finally disappeared.

“While a lack of cooperation between the health authorities and the milkmen is ordinarily the factor which retards improvement in city milk supplies, the limit of improvement is set by the disinclination of the consumer to pay a fair price for the labor and expense necessary in the production and sale of clean milk.”

A method is suggested for encouraging dairymen to have their cows tuberculin tested.

Notices of judgment (U. S. Dept. Agr., Notices of Judgment 847, 867, p. 1 each).—These relate to the adulteration of milk.

Cheddar cheese, W. W. Jenks et al. (X. Y. Produce Rev. and Amer. Cream., 31 (1911), No. 25, pp. 898, 399).—A symposium as to the definition of the term Cheddar cheese.

Note on Gorgonzola cheese, E. Hinks (Analyt. 36 (1911), No. 419, pp. 61–63).—Analyses of Gorgonzola cheese are reported. The average composition of 8 samples of the rind when coated with barytes was as follows: Barytes 83.6 per cent, fat 15.6 per cent, and moisture 0.8 per cent. The methods of making the cheese and applying the coat of barytes are described.

VETERINARY MEDICINE.

General microbiology. W. Kruke (Allgemeine Mikrobiologie. Leipsic, 1910, pp. XV+1184).—This work has to do with the study of matter and energy exchange of the minute organisms, and has been prepared especially for the use of physicians and naturalists. It contains among its chapters the following subjects: The structure, microchemical behavior, and nutrients of micro-organisms; chemical composition of micro-organisms; metabolic processes in micro-organisms; changes wrought by micro-organisms with carbohydrates, alcohols, fats, fatty acids, glucosids, aromatic bodies, proteins, simple nitrogenous bodies, and sulphur and other inorganic substances. The book further considers the channels of oxygen and their relation to the matter and energy exchange, fermentations, coloring matters, poisons (endo-, ecto-, immuno-, tetanus, paratyphoid, erysipelas, anthrax, streptococcus, meningococcus, pyocyanus,
tuberculosis, glanders, ray fungus, mold fungl, and protozoan toxins), hemolysins, hemoglobin, leucocidins, and aggressins.

The work ends with a chapter on the transformability of micro-organisms.

The Ehrlich-Hata preparation 606, R. Lüders (Ztschr. Offentl. Chem., 17 (1911), No. 4, pp. 64–70).—This is a detailed discussion in regard to this preparation and its position in the field of chemotherapy.

Meat poisoning caused by Proteus vulgaris, G. Mazzini (Abs. in Rul. Inst. Pasteur, 9 (1911), No. 4, p. 185).—The author considers the poisoning of some 100 individuals following the consumption of sausages made of pork and beef to have been due to P. vulgaris.

Vaccination against symptomatic anthrax, M. Somogyi (Állatorvosi Lapok, 32 (1909), No. 30, pp. 385, 386; abs. in Berlin. Tierärztl. Wchnschr., 27 (1911), No. 11, p. 193).—During the last few years in the vicinity where the author is active, floods were frequent and following them cases of blackleg have always occurred. The author has attempted to reduce the mortality from the disease by protective vaccination.

In all, nearly 1,500 animals were vaccinated, at first with the vaccine (muscle product) from the Royal Bacteriological Laboratory, and later from the Pasteur-Chamberland Institute. At the outset with the first vaccine everything was satisfactory. Very few animals died from 3 to 4 days after the vaccination. With the second and later vaccinations it was noted that at the site of the vaccination a large swelling always occurred, and the number of deaths became very frequent. This prompted the author to return to the Royal Bacteriological Institute's vaccine, and with which very few deaths occurred.

Vaccinating against anthrax, J. Schnürer (Tierärztl. Zentralbl., 33 (1910), No. 27, pp. 424, 425; abs. in Berlin. Tierärztl. Wchnschr., 27 (1911), No. 11, p. 193).—A description of cases of anthrax in horses and bovines which were vaccinated according to Soberneheim, with anthrax serum (Jenner-Pasteur and Pasteur-Chamberland, both from Budapest), and according to Pasteur (Vaccine I and II). The results obtained were in most instances good.

Foot-and-mouth disease during 1910, Neumann (Berlin. Tierärztl. Wchnschr., 27 (1911), No. 11, pp. 185–189).—This is a discussion in regard to the occurrence and extent of foot-and-mouth disease in Germany, especially in East Germany, during 1910. A comparison is made with Austria-Hungary.

The precipitation reaction for glanders and its practical diagnostic significance, F. Stolpin (Die Präzipitation beim Rotz und ihre praktisch-diagnostische Bedeutung. Inaug. Diss., Dorpat, 1910; abs. in Ztschr. Immunitätsf. u. Expt. Ther., II, Ref., 3 (1910), No. 9, p. 899).—The experiments, which were conducted with horses, cats, rabbits, and guinea pigs (the serum of the last 3 being examined before and after the injection with the precipitation layer test), showed that only animals having the disease yield a specific positive ring test. A positive test was obtained in the case of the cats and guinea pigs 4 days after the infection.

As the precipitogen reagents the author utilized mallein and extracts of 3-day-old Bacillus mallei. Bouillon cultures yielded (with and without glycerin) more potent extracts than agar cultures. See also previous notes (E. S. R., 20, p. 385; 24, p. 481; 25, p. 181).

In regard to utilizing passive anaphylaxis for diagnosing glanders, A. Wladimiroff (St. Petersb. Med. Wchnschr., 35 (1910), No. 45, pp. 608, 609; abs. in Ztschr. Immunitätsf. u. Expt. Ther., II, Ref., 3 (1910), No. 9, p. 902).—The author concludes that passive anaphylaxis can not be employed for diagnosing glanders.

After describing the findings of various investigators in regard to Lentz’s bodies (E. S. R., 22, p. 283), the author states that as a result of his investigations he finds that the views of Lentz in regard to the specificity of the bodies isolated by him are correct.

**The mortality and the incubation period of rabies in man**, S. KOZEWALOFF (Centbl. Bakt. [etc.], 1. Abt., Orig., 57 (1911), No. 5, pp. 893–397).—This paper analyzes the results obtained at the antirabies station at Charkow, Russia, extending over a period of 21 years (1888 to 1908) with 25,608 persons, 24,651 of which were bitten, while the remainder came in contact with rabid animals in some way or other.

The chief disseminators of the virus were dogs (90.6 per cent), cats (6.1 per cent), and wolves (1.2 per cent), the remaining animals mentioned being horses, bovines, pigs, etc. Of the persons bitten and treated 260 died, and of these 161 died 15 days after the final injection was made. The greatest percentage died as a result of the wolf bite, while no deaths were due to the bites of the bovine, horse, pig, etc. The localities bitten were highest for the upper extremities and least for the trunk. The period of incubation was studied in 212 fatal cases, and in most instances (40.6 per cent) this was found to vary from 20 to 40 days. A minimum of 12 days was found in a 3-year-old girl and a maximum with 8 cases of over 200 days.

**The effect of vacuum desiccation upon the virus of rabies**, with remarks upon a new method, D. L. HARRIS and L. F. SHACKELL (Jour. Amer. Pub. Health Assoc., 1 (1911), No. 1, pp. 52, 53).—The method used was as follows:

The material to be dried was placed in the bottom of a Schneibler’s vacuum desiccating jar, in the upper part of which was a separate dish containing H₂SO₄; the temperature was reduced by placing the jar, half submerged, in a salt and ice mixture, and after thorough solidification of the material had resulted, a rapid vacuum was produced by a Geryk pump to less than 2 mm. of mercury. During the process of desiccation, the temperature in the lower half is kept several degrees below 0° C. Unless the H₂SO₄ be repeatedly shaken to prevent surface saturation with water, the time required for complete desiccation will be unduly prolonged.

The authors found that “by using Shackell’s method of desiccation, brains and cords may be desiccated in toto without destruction of virulence. The time required for the complete extraction of water is about 24 to 36 hours. A number of brains have been so treated and the infectivity of all has been preserved. After the completion of desiccation, the brains are placed in an ordinary desiccating jar over H₂SO₄, and left continually exposed to light at the ordinary room temperature.”

Investigations in regard to the infectiousness of street virus for white mice when injected subcutaneously, S. KOZEWALOFF (Centbl. Bakt. [etc.], 1. Abt., Orig., 57 (1911), No. 5, pp. 397–492).—These investigations were made with street virus and virus fixe, and tend to show that white mice are receptive subcutaneously for street virus, but that this method is not so good as the classical, subdural infection of rabbits.

The life history of Trypanosoma gambiense and T. rhodesiense as seen in rats and guinea pigs, H. B. FANTHAM (Proc. Roy. Soc. [London], Sec. B, 83 (1911), No. B 563, pp. 212–227, pl. 1).—“Nonflagellate stages of trypanosomes, such as T. gambiense and T. rhodesiense occur. These nonflagellate stages (‘latent bodies’ of Moore and Breinl) are especially found in the lungs, spleen, and bone marrow during periods of decrease of trypanosomes in the peripheral blood of the host. They are in process of formation at or near the time when the trypanosomes are most numerous in the peripheral blood. The formation of latent bodies takes place especially in the lungs, and they collect in the
spleen and bone marrow of the host. In the formation of nonflagellate stages, some of the cytoplasm and the flagellum of the trypansome are disintegrated. The nonflagellate body contains the nucleus and blepharoplast (kinetonucleus) of the trypansome. Nonflagellate (latent) bodies can be seen to grow and flagellate, turning into trypanosomes, when placed in fresh, warm, uninfected blood. Latent bodies of *T. rhodesiense*, inoculated into a rat, flagellate and produce trypanosomiasis. The nonflagellate (latent) bodies of trypanosomes (*T. gambiense* and *T. rhodesiense*) are the postflagellate stages of one generation of trypanosomes and the preflagellate stages of the succeeding generation of trypanosomes. There is a life cycle of trypanosomes (*T. gambiense* and *T. rhodesiense*) in vertebrate hosts, comparable with those of *Crithidia* and *Herpetomonas* in the alimentary tracts of various invertebrates. The latent (relatively resistant) stages of trypanosomes occurring in invertebrates are separate from, and in addition to, stages of the parasite which may occur in the invertebrate carrier (for example, Glossina).

Results obtained from the inoculation of dogs with the horse sickness virus, P. and E. Kuhn (Ztschr. Immunitätsf. u. Expt. Ther., I. Orig., 8 (1911), No. 5–6, pp. 665–739).—The authors find that horse sickness can be transmitted to dogs through ingestion of the virus. They think that the native jackal, a related species of Canis, may be found to be a carrier of the virus.

Notes on the bovine plasmoses of Southern Rhodesia, L. E. W. Bevan (Rhodesia Agr. Jour., 8 (1910), No. 1, pp. 74–81).—The author concludes that "young cattle bred in Mashonaland, while themselves tolerant or immune, harbor in their blood at least 2 species of protozoa, namely, *Piroplasma bigeminum* and *Anaplasma marginale*. Blood taken from them and inoculated into susceptible animals gives rise to 2 infections. That caused by *P. bigeminum* occurs first, and that caused by *A. marginale* follows at a time when the subject is weakened by the *bigeminum* infection. Great care is necessary in the selection of blood for inoculation purposes. The constitution and breed of the animal supplying the blood, its origin, and the approximate degree of infection to which it has been submitted since birth, must be taken into consideration, but it is possible to find a blood in which the parasites are attenuated or of sufficiently low pathogenicity to produce an infection which can be regulated.

"The process of immunizing can not be conducted on mechanical lines, but each case must be treated 'on its merits.' The individual resistance of the animal to be inoculated bears an important part. When undergoing the process of inoculation the animal must be kept free from ticks; and even when immunized, a gross infestation by ticks is to be avoided, as the immunity is likely to break down under severe infection. The process of immunizing involves a severe strain on the animal's system, and checks development. Some of the drugs regarded as specifics against *P. bigeminum* are not specific against allied parasites."

In regard to differentiating the tubercle bacilli from various sources with the aid of bile containing nutrient media, P. Meyer (Über die Differenzierung der Tuberkelbakterien verschiedener Herkunft auf gallenhaltigen Nährböden. Inaug. Diss., Giessen, 1910, pp. 38; abs. in Ztschr. Tuberkulose, 17 (1911), No. 2, p. 187).—The bile of the human being, bovine, dog, fowl, pig, and sheep in ordinary media in most instances partially inhibits the growth of the tubercle bacillus from bovine, human, and avian sources. The inhibition varies with the source of the bile, and particularly when the bile of one animal species is employed for cultivating the tubercle bacillus obtained from another animal species.

In regard to combating bovine tuberculosis, M. Klimmer (Schweiz. Arch. Tierheilk., 52 (1910), No. 6, pp. 382–406, fig. 2; abs. in Ztschr. Immunitätsf. u.
Expt. Ther., II, Ref., 3 (1910), No. 13, p. 1099).—The author in this article recommends the use of antiphymatol for vaccinating against tuberculosis. The active principle of this preparation is obtained from human tubercle bacilli which have been prepared by passing them through cold-blooded animals and subjecting them to low temperatures, as a result of which the bacteria lose their infectious characters. The bacteria so prepared, according to the author, do not multiply when introduced into the system. He points out the limitations of this preparation and of its use as a curative agent.

Antiphymatol (Klimmer) and Klimmer's segregation method, E. Hauptmann (Tierzücht. Zeitschr., 33 (1910), Nos. 34, pp. 534-550; 35, pp. 559-563; abs. in Ztschr. Immunitätst. u. Expt. Ther., II, Ref., 3 (1910), No. 13, pp. 1095, 1096).—These tests extended over a period of 2 years and were made with 125 bovines, among which, before segregation, 70 per cent gave a positive (phymatin-human) ophthalmic reaction.

Among the 30 animals which at the outset did not react toward phymatin, and which were vaccinated twice the first year and once the following year with antiphymatol, 5 after from 1 to 2 years were found to be sound on slaughter, despite the fact that during the interval the animals were kept in a barn containing diseased animals, some having open tuberculosis. The remaining healthy animals were not affected in the least by the vaccination, with the exception that the yield of milk on the day of the vaccination was decreased an average of 2 liters per head. No hygienic precautions other than the injection were taken with the animals.

Out of 79 animals which gave a positive ophthalmic reaction, 26, among the number 3 clinical cases and 2 enucleated "coughers," were injected 4 times during the first year with antiphymatol in order to determine its curative action. Two of the clinical cases were slaughtered after the second injection and showed widely distributed inflammation of the pleura. The 2 "coughers" which were injected 4 times were found on slaughter to be markedly tuberculous. A clinical case is still living and is in a good constitutional condition. The other clinical case after slaughter and after a period of 1½ years showed capsulated foci. In 7 clinically sound cases ⅔ of a year after the close of the work the same capsulated foci were found after slaughter. The author believes that heavy feeding aided the curative action of this vaccine to a considerable extent.

The remaining 53 reacting animals were injected twice. Five were slaughtered, and 4 of these showed calcified foci, while the fifth was macroscopically free from tuberculosis. Thirteen of the living animals are in very good shape, while the remainder are in a fair state of preservation.

Diseases of the cow (excluding tuberculosis) affecting the milk in their relationship to human diseases, W. G. Savage (Jour. Meat and Milk Hyg., 1 (1911), Nos. 4, pp. 175-191; 5, pp. 231-241).—This article discusses the various nontubercular diseases occurring in cows, such as anthrax, Gaertner infections, gastro-enteritis, Malta fever, mastitis, ulcerated teats, and sore throat, with particular reference to their relation to the production of disease in man by way of the milk from such animals.

A number of outbreaks are cited which had their origin from the cow.

Researches on the etiology of cachexia aquosa of ruminants.—The rôle of worms in gastro-intestinal strongylosis of sheep, Cuillé, Marotel, and Panisset (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 14, pp. 567, 568).—The authors have determined that the disease known as cachexia aquosa, which seriously affected ruminants during 1910, is not entirely dependent upon the presence of the liver fluke. In all the cachectic animals examined numerous
helminths, etc., of various species were found, including a new strongyloid species discovered in the abomasum.

The intermediate host of the liver fluke, Distoma (Fasciola) hepaticum, in South Africa, J. D. F. Gilchrist (Agr. Jour. Cape Good Hope, 37 (1910), No. 6, pp. 658, 659, fig. 1; Vct. Jour., 67 (1911), No. 430, pp. 249, 250).—The snail Physa tropica has been found by the author to be the intermediate host of the liver fluke in Cape Colony.

In regard to the causative agent of hog cholera, Küther (Berlin. Tierärztl. Wochenschr., 27 (1911), No. 11, pp. 191, 192).—A review of the more recent literature.

Protective vaccination against hog cholera, D. Szabó (Állatorvosi Lapok, 33 (1910), No. 1, pp. 4, 5; abs. in Berlin. Tierärztl. Wochenschr., 27 (1911), No. 11, p. 194).—After separating the sick hogs, the remainder, with the exception of 30, were treated with Hutyra's vaccine (20 cc. of defibrinated blood). Of the 30 hogs not sick and not vaccinated 60 per cent died, of the 169 vaccinated but not sick animals only 13.8 per cent, and of the 26 sick and vaccinated animals 84.6 per cent.

Tests with Suptol-Burow, I. Weiss (Állatorvosi Lapok, 33 (1910), No. 16, pp. 183, 184; abs. in Berlin. Tierärztl. Wochenschr., 27 (1911), No. 11, p. 193).—Suptol-Burow was found to be without value in cases of either pure septicemia or mixed infection, whether as a protective or as an agent for conferring permanent immunity against swine plague. See also a note by Tillmann (E. S. R., 24, p. 455).

The occurrence of the ox warble in the brain of a horse, P. Grinsted (Mudderdschr. Dypllage, 22 (1910), No. 12, pp. 305-308; abs. in Berlin. Tierärztl. Wochenschr., 27 (1911), No. 9, p. 153).—The author reports a case in which at post-mortem a larva of Hypoderma bovis, 12 mm. in length, was taken from the right temporal lobe.

Treatment of canine distemper with Deutschmann's antistreptococcic serum and with permanent yeast (Antigourmine), F. Lamche (Vorbeugung und Behandlung der Hundestampe mit Deutschmann’s Antistreptokokkenserum und mit der Dauchhüte “Antigourmine,” Inaug. Diss., Zürich, 1909; abs. in Berlin. Tierärztl. Wochenschr., 27 (1911), No. 11, pp. 193, 194).—This discusses the preparation of Deutschmann's polyvalent antistreptococcic serum from yeast, and of Antigourmine, which is a permanent yeast preparation.

The results with the polyvalent serum show that the serum can be used without danger for a long period of time, but that it is of no value for diseases of the digestive tract, even when these occur as complications of the lung affections. It has a favorable effect upon cases of distemper-pneumonia. The inflammations of the lung heal quicker and better under the influence of the serum, and inflamed corneas and corneal ulcers are either checked in their development or are stimulated to rapid healing. The course of the distemper pustules is not affected.

Antigourmine was found to be absolutely inactive as a prophylactic or as a therapeutic agent against distemper.

Fowl diphtheria and fowl pox, I. Rázt (Állatorvosi Lapok, 33 (1910), No. 16, pp. 184-186, figs. 2; abs. in Berlin. Tierärztl. Wochenschr., 27 (1911), No. 12, pp. 208, 209).—These investigations verify the assumption that fowl diphtheria and pox (gregarinosis) are produced by the same filterable virus. By transferring the diphtheric membrane to sound animals the author was able to produce changes which simulated those characteristic of fowl pox, and with the virus of fowl pox he produced characteristic diphtheric lesions.
Experimental contribution in regard to the identity of fowl cholera and fowl pox, H. SiGWART (Centbl. Bakt. [etc.], 1. Abt., Orig., 56 (1910), No. 5-6, pp. 428-464; abs. in Berlin. Tierärztl. Wchnschr., 27 (1911), No. 12, p. 208).—The cases examined came from various parts of South Germany. Experimental tests were made with sound birds from $\frac{1}{3}$ to 1 year old, and with pathologic material (pocks, pock scabs, diphtheric membranes, nasal and tracheal secretions, and blood which was obtained under sterile conditions) rubbed up in physiological salt solution.

The results show that fowl pox can occur as a pure skin disease, or it can simply attack the mucus membranes of the head. The disease may also be present in both regions at the same time. The chronic cases without mucus membrane involvement were found to be in most instances mild forms of the disease.

Inoculation tests showed that when the infection is made on the comb the disease assumes the chronic membranous form of the head, but as infection does not always take place the author points out that this fact must not be considered a proof of the occurrence of idiopathic cases. Infection is not always possible with the liver and blood from chronic cases of the disease, and where infection did occur the disease usually ran a mild course.

After infecting intravenously with the pox virus in most instances no dermal changes took place. The only parts affected were the mucus membranes of the head, and this was irrespective of whether the infecting virus came from the skin form of the disease or from the membranous form. More positive results were obtained with the filtered pox or membrane virus, but in most instances the disease ran a mild course.

From the immunity tests it could be noted that a pure case of the disease can confer absolute immunity against infection cutaneously, per comb, face, and wattles. The duration and degree of immunity are relative to the degree of the disease. Mild forms of the disease do not always confer immunity.

In regard to protective vaccination against fowl cholera, K. KovÁRZIK (Allatorvosi Lapok, 33 (1910), No. 32, pp. 375-339; abs. in Berlin, Tierärztl. Wchnschr., 27 (1911), No. 11, p. 194).—During the year 1909 from 50 to 90 per cent of the fowls of the district under observation were affected with fowl cholera. In some of the pens from 8 to 13 per cent of the birds were immune.

The author made tests with Galloserin, and found that the vaccinated animals became immune in from 2 to 5 months. No favorable results were obtained with animals already diseased. The procedure is considered too expensive for ordinary practice.

In regard to a new fowl disease in Europe.—Apoplectic septicemia in fowls, H. MagnuSSon (Centbl. Bakt. [etc.], 1. Abt., Orig., 56 (1910), No. 5-6, pp. 411-428, figs. 5; abs. in Berlin. Tierärztl. Wchnschr., 27 (1911), No. 12, p. 209).—A study in regard to a disease which has been rarely observed and which is caused by a streptococcus. This organism could not be differentiated from the usual pathogenic streptococci, and according to the author the disease is due to a casual increase in the virulence of this streptococcus, which usually inhabits the intestinal tract of fowls, but where it is mostly latent.

RURAL ENGINEERING.

Elements of agricultural technology, C. A. Vogler et al. (Grundlehren der Kulturtechnik. Berlin, 1909, 4. ed., vol. 1, pts. 1, pp. XIX+539, pls. 3, figs. 205; 2, pp. X+804, pls. 6, figs. 707).—This handbook is designed particularly for the 7717°—No. 5—11—7
use of the agricultural engineer, and summarizes a large amount of available data. Part 1 is devoted to the more general scientific phases of the subject, and especially to soil formation, agricultural botany, and the principles of mechanics and hydraulics. Part 2 discusses specific engineering problems, including roads, irrigation, drainage, moor culture, and land surveying.

Irrigation in Arizona, R. H. Forbes (U. S. Dept. Agr., Office Exp. Sta. Bul. 235, pp. 83, pls. 4, figs. 8).—This is one of the series of reports prepared in this Office for the purpose of giving general information regarding the opportunities for settlement on irrigated lands in the several Western States and Territories, the cost of land and water and of establishing homes on these lands, and regarding the crops grown. It discusses the history of irrigation development in Arizona, the area and topography, flora, industries, valuations, and population of the Territory, its climate, crops, markets, lands, and water resources, the laws and usages relating to irrigation, existing irrigation enterprises, and agricultural practice, and the agricultural present and future.

The water supply of Arizona available for irrigation purposes is estimated at from four to five million acre-feet a year, or sufficient for from $60,000 to 1,000,000 acres, whereas it is estimated that in 1900 but 227,770 acres was actually cultivated. “Five times the present area of doubly productive land will yield an annual product worth $90,000,000, which, with a possible output of $20,000,000 annually from grazing ranges, would give a total for the agricultural industries of over $100,000,000 annually. This is well in excess of the mining output of the Territory at the present time and suggests the possibility that finally in Arizona, as in the once mining States of California and Colorado, agriculture will become the leading industry.”

Irrigation in California, F. W. Roeding (U. S. Dept. Agr., Office Exp. Sta. Bul. 237, pp. 62, pl. 1, figs. 17).—This is another of the series of reports dealing with irrigation in the arid States and Territories, and has been prepared by this Office in cooperation with the State of California for the purpose of answering inquiries regarding conditions and the opportunities and cost of settlement.

Following a general discussion of the climate, population, industries, assessed valuation, and transportation facilities of the State, the water resources, lands, and products are discussed in detail, together with the history of irrigation development, water laws, various irrigation enterprises, and the cost of preparing land for irrigation.

The area of irrigable lands in California under present systems is computed to be 3,876,000 acres, of which about 2,500,000 are being actually irrigated. “With better laws to control and regulate diversions from the streams of the State, and therefore a guaranty for the safe investment of capital in irrigation enterprises without expensive litigations which have been incident heretofore with appropriations from the natural water courses, the State can expect a much larger population throughout the agricultural districts and a great addition to its wealth.”

The use of underground water for irrigation at Pomona, Cal., C. E. Tair (U. S. Dept. Agr., Office Exp. Sta. Bul. 236, pp. 99, pls. 5, figs. 8).—The work upon which this report is based was done in cooperation between this Office and the State of California.

“The Pomona Valley is typical of localities in the citrus belt of southern California, where water has a high agricultural value, but can be secured only at high cost. Much of the water is pumped, and there is no other section where water is used more economically or where greater effort is made to improve methods of development, distribution, and application. This report describes the problems confronting the irrigators, the methods employed, and the progress made in the economical use of the water resources.”
Data are presented as to the duty of water for various crops, showing the use of from 0.8 to 0.82 ft. for citrus fruits, 0.45 ft. for deciduous fruits and diversified crops, and from 2.3 to 2.4 ft. for alfalfa. The cost of irrigation under prevailing methods is computed to be $24 per acre for oranges and $35 per acre for alfalfa.

It is maintained that the quantity of water being used is closely approaching the limit of the available supply, though some improvement is possible through conservation as well as by the construction of storage works. "But there must be an end to such works, and the extreme measures taken emphasize the fact of the scarcity of water to be had in large quantities. About 250,000 acres are now irrigated in the coast region of southern California. Work now progressing and other possible developments may add another 150,000, but finally the only possible further increase must come from a more economical use of the water available. Little improvement can be made over the best systems now in use in the transmission of the water from its source to its point of use. The greatest opportunity for saving is in a more economical application of the water to the land, and, moreover, whatever may be saved is as useful in the development of additional territory as the same amount of water from new sources, and it may be cheaper."

Irrigation in the San Joaquin Valley, California, V. M. Cone (U. S. Dept. Agr., Office Expplt. Stats. Bul. 239, pp. 62, pl. 1, figs. 15).—This bulletin reports cooperative work between this Office and the State of California.

"The San Joaquin Valley includes nearly half the valley lands of California, and is noted for its productivity and adaptability to a wide range of crops. Irrigation, however, is necessary throughout the greater part of the valley to bring about the highest development. This report shows the possibilities and advantages of irrigation and the cost of water."

Data are given as to the climate, soils, water resources, population, transportation facilities, and agricultural and horticultural development of the valley, with details as to the streams and the lands irrigated by them. About 4,800,000 of the 7,360,000 acres in the floor of the valley are irrigable. Agricultural development is, however, handicapped by lack of state control of the water resources and the prevalence of wasteful methods and much litigation. "Wasteful methods have resulted in waterlogging large portions of the older irrigated sections, and but little effort has been extended toward restoring them to their former state of productiveness. Drainage, therefore, is emphatically needed and should go hand in hand with irrigation as a prevention and cure for such damage. . . .

"The San Joaquin Valley has made a great growth. The acreage under irrigation is increasing each year, and in the irrigated sections there is apparent progress and prosperity. A large acreage is being planted to vines and trees and other permanent crops, and much care and intelligence are shown in the work. The natural advantages of the valley will insure its continued progress, but it cannot reach the development of which it is possible and provide homes for the greatest number unless some of the handicaps are removed."

Agricultural observations on the Truckee-Carson irrigation project, F. B. Headley and V. Fulkerson (U. S. Dept. Agr., Bur. Plant Indus. Circ. 78, pp. 29, fig. 1).—This circular presents data and agricultural observations on the Truckee-Carson irrigation project in western Nevada, particularly as noted at the experiment farm operated at Fallon, Nev., in cooperation with the Nevada Station (E. S. R., 22, p. 35). It describes the physical features of the project, showing the object and result of tree planting and what success may be expected with forage crops, vegetables, and fruits. It is shown that practically
all of the land available has been taken up, about 35,000 or 40,000 acres being now under cultivation.

It is shown that at a cost of about $1.50 per acre an 8-acre field was dynamited by placing the dynamite in the ground from 2 to 6 ft. deep and at distances of from 20 to 30 ft. “When the fall and spring rains came the water, which formerly stood for days on the ground, was immediately absorbed, leaving the field dry and apparently in good condition.” “The yield per acre has shown a marked increase.”

The mechanical culture of the soil, M. Ringelmann (Rev. Sci. [Paris], 49 (1911), I. No. 11, pp. 336-339).—This article deals briefly with the applications of various kinds of mechanical power to farm work.

Working trials with hay-harvesting machinery, C. V. Birk and M. Dall (Tidsskr. Landföknomi, 1911, No. 6, pp. 377-400, figs. 11).—This report gives the results of trials of 9 different rakes, mostly side-delivery rakes, and describes each.

[The cost and net returns of agricultural work] (Journ. Soc. Agr. Brabant et Hainaut, 55 (1910), No. 52, p. 1272; 56 (1911). No. 1, pp. 5, 6).—The article discusses the relative economy of having work done by a labor-saving machine and by hand labor, as illustrated by machinery for cutting hay, harvesting, and other agricultural machinery.

Practical silo construction, A. A. Houghton (New York, 1911, pp. 69, figs. 18).—A treatise on simple and practical methods of constructing concrete silos of all types, with unpatented forms and molds.

The kind of wood for a silo, E. A. Burnett (Breeder's Gaz., 59 (1911), No. 16, p. 1002).—A discussion of the durability of different kinds of wood commonly used for building silos.

The new cement manure shed at Flahult, H. von Feilitzen (Svenska Mosskulturför., Tidsskr., 25 (1911), No. 2, pp. 135-141, figs. 2).—A description of the manure shed with illustrations is given. The area of the shed is 11 by 11 meters (about 43.3 ft. square), or 4 square meters per animal for a herd of 30 cows.

The destruction of hydraulic cements by the action of alkali salts, E. Burke and R. M. Pinckney (Montana Sta. Bul. 81, pp. 77-131, figs. 16).—This bulletin, continuing work previously reported (E. S. R., 20, p. 288), deals in definite order with the chemical changes which bring about the disintegration of cement. In the work Portland, slag, and natural cements were used, being tested in regard to their resistance to sea water and various salts, including sodium sulphate, magnesium sulphate, sodium carbonate, sodium chlorid, calcium hydrate, and calcium sulphate, in solutions of various concentrations.

The authors point out that the disintegration of cement by alkali salts is chiefly due to the reaction of these salts with the calcium hydroxid of the cement. As a result of these reactions, relatively insoluble new compounds having greater weight and bulk than calcium hydroxid are formed, and force apart the particles of cement and thus weaken or break the binding material. The binding material is in some instances leached out. As a result of these interactions with calcium hydroxid, sodium sulphate when present produces sodium hydroxid and gypsum, magnesium sulphate produces magnesium hydroxid and gypsum, and sodium carbonate produces sodium hydroxid and calcium carbonate. In the last-named instance, however, there is little increase in bulk, but instead the silicates and aluminates are attacked and dissolved.
In order for destructive action to become marked the alkali solutions must percolate through the cement work, or at least must penetrate beyond the surface. When the action is strictly confined to the surface, as when briquets of neat cement are immersed in a still solution, the tensile strength may be increased. In such cases the expansive action closes up the pores, making the surface more nearly impervious and preventing the alkali from penetrating further. When cracks are started by the expansive action due to alkali salts, wetting and drying, or freezing and thawing, will hasten the destruction of the cement by extending the cracks already started.

Any measures that hinder the penetration of the alkali solutions into the interior of the cement will delay the destructive action. For this purpose both soap and aluminum sulphate were tried in laboratory tests and found to afford some protection. The soap, however, in itself had a slightly injurious effect on the tensile strength of the cement. The efficiency of these and of other waterproofers is being further studied [by the authors] and results will be reported in a later bulletin.

The materials of paint manufacture, G. B. Heckel (Jour. Franklin Inst., 171 (1911), No. 6, pp. 559-614).—A digest of data regarding the materials used and the processes followed in the manufacture of paint.

Plumbing and household sanitation, J. P. Putnam (Garden City, N. Y., 1911, pp. 718, pl. 1, figs. 652).—Historical data, theories which have to do with the general subject of plumbing, and practical and theoretical plumbing problems are discussed in this volume, which represents a course of lectures delivered before the Plumbing School of the North End Union, Boston.

The process of disinfection by chemical agencies and hot water, Harriette Chick (Jour. Hyg. [Cambridge], 10 (1910), No. 2, pp. 237-286, dpms. 21).—Studies are reported of disinfection with phenol, hot water, and sunlight and drying.

A general conclusion reached is that "disinfection, whether by disinfectants or by heat, may be considered analogous to a chemical reaction the velocity of which is controlled by external conditions such as temperature or concentration of bacteria and disinfectant."

Kitchens and laundries—their planning, arrangement, equipment, and sanitation, W. P. Gerhard (Dom. Engin., Philadelphia Ed., 48 (1909), Nos. 3, pp. 62-69, figs. 16; 7, pp. 182-184, fig. 1; Eastern Ed., 50 (1910), No. 3, pp. 61-66, figs. 10; 53 (1910), Nos. 2, pp. 35-39, figs. 5; 3, pp. 63-66, figs. 11; 9, pp. 221-225, figs. 11; 51 (1911), Nos. 3, pp. 54-58, figs. 16; 7, pp. 178, 179; 8, pp. 207-219, fig. 7).—In this exhaustive discussion of the subject hotels and public institutions are considered as well as home kitchens and laundries.

Chapters are devoted to cooking with different fuels and with electricity. The text is supplemented by numerous plans and illustrations.

RURAL ECONOMICS.
population from 15 to 50 years is exactly the same (39/100) as that for the rest of the population."

It is held that it has degraded the all-around man productively in order to admit greater economic production. Because of the nature of its work agriculture prohibits the application of the law. It thereby forces the farm laborer to possess a greater degree of application and a greater breadth of view than is required of a laborer in almost any other industry, as agricultural wages are not commensurate with the value of the services and in proportion to other wage labor. This is illustrated by showing that the common rate of wages in many factories is 19 cents an hour for 9 hours' work per day, or $45.50 per month of 224 hours, while the prevailing wages of a dairy farmer are 13 cents an hour of 11 hours per day, or $39.25 per month of 302 work hours. The law also has the effect of inducing labor to migrate from the farm to the factory and in turn drives back to the farm the poorest elements of labor that have offered themselves to the factory.

The agricultural labor question (Zitschr. Landw. Kammer Braunschweig, 79 (1910), No. 27, pp. 329-331).—This article discusses the labor problem in its various aspects, showing the tendency of agricultural labor to migrate to towns and cities. It is pointed out that of the total number of inhabitants in Prussia in 1849 71.93 per cent were living in rural districts; in 1871, 67.57 per cent; in 1900, 56.93 per cent; and in 1905, 54.77 per cent.

The colonization of the United States, A. K. Eckerboom (Den Inre Kolonisationen i Förenta Staterna. Stockholm, 1909, pp. 114).—This report, which is issued by the Swedish Committee on Emigration, gives a detailed account and discussion of the occupation of the agricultural land in the United States, the homestead laws, and the economic status of the settlers. A bibliography on the subject is appended.

Changes in agricultural industry, Great Britain, J. L. Griffiths (Daily Cons. and Trade Rpts. [U. S.], 14 (1911), No. 131, pp. 1025, 1026).—This report discusses important changes that have occurred in the agricultural industry of Great Britain within the last decade, the most conspicuous being the decrease in arable land (932,110 acres) and in wheat growing (247,990 acres), and the increase in orchard and small fruits (36,472 acres).

A growing tendency for small agricultural holdings to displace the large landed estates is noted, as within the last 25 years 1,795 farms of over 300 acres each have been broken up and at the present time but little more than 3 per cent of the agricultural holdings can be described as large farms. The number of small holdings of more than one acre increased from 590,508 to 510,445 during 1910, notwithstanding there was a reduction in the same period of 37,143 acres in the farmed area of the country.

[Report of agricultural special agents in Spain] (Bol. Agr. Téc. y Econ., 2 (1910), No. 22, pp. 315-522).—This is a statistical report based on data submitted by agricultural engineers in the various provinces of Spain relative to acreage, production, etc., of agricultural products on dry and irrigated lands.

The economic position of Danish agriculture, C. Sonne (Tidsskr. Landb-konon, 1911, No. 2, pp. 98-120).—This is a careful and comprehensive discus-
sion of the present economic status of Danish agriculture, based on comparisons between the production and values during the 2 years 1887–8 and 1907–8. The author concludes that marked progress has been made and that the present condition of Danish agriculture is, on the whole, founded on sound economic principles.

Report on the trade and commerce of Denmark for the year 1910, L. C. Liddell (Diplo. and Cons. Rpts. [London], Ann. Ser., 1911, No. 4642, pp. 50, pl. 1).—In addition to export and import statistics the report gives a detailed review of the agricultural pursuits in Denmark during the year 1910, and how they were affected by tariff reform and other legislation in neighboring states and foreign countries.

It is stated that the cooperative movement has caused the abandonment of some and the development of other agricultural pursuits, and that it has given a stimulus to export trade of agricultural pursuits generally. Data are given as to the work and progress of various cooperative societies, and the number, membership, capital, etc., of each. While some have not paid dividends others have paid as high as 15 per cent, the average of those reported being over 6 per cent. The accounts of the rural cooperative fire insurance societies show a deficit because in fixing the premiums the increased risk of danger from fire to thatched buildings, as the use of agricultural machinery increases, was not taken into consideration.

Report on the trade and commerce of Porto Rico for the year 1910, Churchward (Diplo. and Cons. Rpts. [London], Ann. Ser., 1911, No. 4657, pp. 22, pl. 1).—The report contains general agricultural statistics of Porto Rico for 1910, export and import statistics, and data as to wages and labor conditions. It is stated that the supply of labor of all kinds is plentiful, but that some difficulties have been encountered in connection with it because of labor organizations.

Report of the Irish Agricultural Organization Society, Limited, for the year ending June 30, 1910 (Rpt. Irish Agr. Organ. Soc., 1910, pp. 144).—This report reviews the work of various kinds of agricultural societies and credit societies in Ireland for the year ended June 30, 1910, together with committee reports and discussions pointing out the merits and defects of the actual operation of particular kinds of cooperative organizations.

Agricultural prices (Ireland), Newman (Dept. Agr. and Tech. Instr. Ireland, Agr. Prices, 1881–1909, pp. 6).—This is a report showing the annual price of live stock and agricultural products in Ireland for each year from 1881 to 1909, and the annual average prices for various intervals during this period.

The prices of farm products, H. C. Taylor (Wisconsin Sta. Bul, 209, pp. 3–30, figs. 14).—This bulletin discusses and illustrates the factors which determine the prices of farm products, the relation between prices and farm management, and the forces which influence the supply and price of eggs, butter, potatoes, corn, and other farm products.

Crop Reporter (U. S. Dept. Agr., Bur. Statis. Crop Reporter, 13 (1911), No. 6, pp. 41–48).—Statistics are given on the condition of crops in the United States and foreign countries; the farm value of important products in various places in the United States and at specified times during 1910–11; temperature and precipitation statistics; the cost of producing oats in the different States
and Territories in 1909; monthly receipts and stocks of eggs and poultry in the
principal cities of the United States; and range of prices of agricultural prod-
ucts for a period of years.

AGRICULTURAL EDUCATION.

A program of agricultural progress, J. Hamilton (W. Va. Univ. Bul., 9,
ser., 1910, No. 9, pp. 12-24).—In this address, delivered at the college of agri-
culture of West Virginia University, the author outlined the needs of agricul-
ture, particularly with reference to restoring fertility, and discussed the
functions of the agricultural college, the agricultural experiment station, the
state department of agriculture, the National Department of Agriculture, and
subordinate agencies in bringing about better conditions.

Agricultural instruction in Algiers (Bul. Agr. Algérie et Tunisie, 16
(1910), No. 12, pp. 296-303).—In this article are discussed the different methods
of disseminating agricultural knowledge throughout the colony, viz, by the
schools of agriculture, departmental and special professors of agriculture, the
School of Sciences of Algiers, the botanical and agricultural stations of Algiers,
agricultural societies, horticultural and agricultural committees, primary
schools, and the annual congress of agriculture held in each of the three prin-
cipal towns of the departments of the colony.

Tenth annual general report of the Department of Agriculture and Tech-
Rpt., 10 (1909-10), pp. VI+490).—This is a report on the department’s admin-
istration and funds, and on details of its work during 1909-10, including agri-
cultural and technical instruction.

The report on agricultural instruction comprises details concerning the work
of individual institutions, special classes, lectures, and practical demonstra-
tions carried out by itinerant instructors in agriculture, horticulture, poultry
keeping, and butter making throughout the country and by agricultural over-
seers in congested districts. At the close of the year 1909-10 the department’s
program of agricultural education had been 10 years in operation, and in some
features of instruction the report gives data for the 10 years, or from the
organization of the instruction, to show the progress made.

Detailed accounts of the work in technical instruction are given in the
reports of inspectors, tables, and appendixes.

The appendixes include statements of the receipts and expenditures under
the department’s parliamentary grant, endowment fund, etc.; the personnel
of the agricultural councils and boards; a table showing by counties the agri-
cultural schemes adopted by the several county committees for 1909, the amount
appropriated from the joint fund for each scheme, and the proportions of the
total appropriation chargeable to local contributions and to the department’s
grant, respectively; schemes of instruction in agricultural subjects; pros-
pectuses of agricultural colleges and stations and schools of rural domestic
economy; agricultural scholarships and apprenticeships; a program of experi-
mental science, drawing, and domestic economy for day secondary schools; a
program for technical schools and science and art schools and classes, including
domestic economy; examples of schemes of technical instruction in nonagri-
cultural subjects, including domestic economy; a list of day secondary schools
showing the grants paid by the department during 1909-10 for instruction in
the subjects of the department’s program, including domestic economy, given
during 1908-9; and a statement showing the occupations of students, including
domestic science classes, attending schools and classes conducted under the con-
ditions of schemes of technical instruction in nonagricultural subjects, etc.
Agriculture in the public schools, G. A. Bricker (Ed. Rev., 41 (1911), No. 4, pp. 395-403).—The author considers that agriculture should be taught in the public schools (1) to solve the problem of intensive agriculture and (2) to prepare young men for the business of farming.

An experiment on methods of teaching zoology, J. P. Gilbert (School Sci. and Math., 11 (1911), No. 3, pp. 205-215).—This is a progress report on an experiment in teaching high-school zoology, undertaken in the school of education at the University of Illinois to determine the relative merits of the pure science and the applied science methods of approach in teaching.

The experiment was made with two approximately equal sections, under conditions as similar as possible, and extended over one semester. Section A, known as the cultural and disciplinary group, studied insects, birds, frogs, and other zoological specimens for the purpose of learning the functions of the different organs and their significance and their adaptations to the struggle for existence. Section B, known as the economic group, studied the same kinds of specimens, in the same way, and raised the same questions, but did not dwell so long on this phase of the work, thus saving time for an inquiry into the economic importance of the phenomena under observation—their applications to agriculture. The results obtained are summarized as follows:

"The results are only suggestive, in view of the small number of individuals tested. Even allowing for the probable error, however, the applied science method of approach to the study of secondary school zoology appears to have a slight advantage over the pure science approach, when tested by examination grades (the examination being of the pure science type). When tested by average semester grades, the applied science approach shows a somewhat greater advantage. When tested by the percentage of pupils averaging more than 85 per cent in the semester's work, the applied science approach has a slight but appreciable advantage."

"When tested by the ability of the pupils to set up experiments and interpret phenomena (a cultural and disciplinary standard), the applied science approach has a decided advantage."

The teacher believes that the method of investigating classroom problems by comparing the progress of parallel groups of pupils may be made to yield valuable results.

The animals and man, V. L. Kellogg (New York, 1911, pp. X+495, pl. 1, figs. 2½).—The book is an elementary textbook of zoology and human physiology.

In part 1 the author discusses the parts of animals and how they are used. Part 2 deals with the life history of animals. In part 3 different kinds of animals are classified and their habits and special relations to man given. Human structure and physiology is considered in part 4, prepared by Isabel McCracken, and part 5 has to do with animals in relation to each other, to plants, and to the outside world. There are also appendixes containing information on school equipment, rearing animals, and making collections.

The use of the score card in rural schools, E. A. Cockefair (Bul. Mo. State Norm. School, Third Dist., 2 (1910), No. 2, pp. 36).—After discussing the functions of agriculture in rural school courses, the author gives specific directions for judging corn, horses, and dairy cattle. In each case a score card is given with detailed explanations of the different points involved in judging.

Domestic science for schools and homes, Gertrude T. Johnson (Kansas City, Mo., 1911, 2, ed., rev. and ed., pp. 153, pls. 2, figs. 32).—This is a text in cooking and a syllabus in sewing, prepared for use in the Kansas City elementary schools. It contains in untechnical language the fundamental theories of foods and their functions, together with more than 200 recipes.
The portion of the book devoted to cooking is divided into 5 parts. Part 1 is a syllabus of the course for the teacher's use, parts 2 and 3 contain lessons for the pupils of the seventh and eighth scholastic years, and part 4 an appendix for the use of classes having more than one lesson per week, for home use, and for general reference. Part 5 describes a light cooking and manual training equipment for classes of 24 pupils. The work in sewing is divided into general suggestions and courses for the sixth, seventh, and eighth scholastic years.

Domestic art in woman's education, Anna M. Cooley (New York, 1911, pp. XI+27½).—The object of this book is to point out the relationship between domestic art and other elementary school subjects and the place it may occupy in high schools, colleges, or trade schools. It is divided into 4 parts. Part 1 discusses problems confronting those interested in teaching domestic art; part 2, on domestic art in the elementary school, deals chiefly with the factors involved in planning courses of study; part 3 treats of the relation of domestic art to secondary education; and part 4 discusses (1) domestic art as a part of college training for women, and (2) domestic art in other higher institutions of learning. A selected bibliography of books helpful in the study of the various phases of domestic art is appended.

A basis of organization of the course in nature study, O. W. Caldwell (Nature-Study Rev., 7 (1911), No. 4, pp. 87-90).—This paper points out that a course in nature study should be organized in a fairly definite way in so far as concerns purposes and the general line of procedure. The native interests of children should be considered, since, though these are not an all-determining factor, they are important and should be utilized.

The children in the grades are accordingly divided into three groups with reference to interest in nature. The first group includes the kindergarten, first and second grades; the second group the third, fourth, and fifth grades; and the third group the sixth, seventh, and eighth grades.

The outlook to nature, L. H. Bailey (New York, 1911, rev. ed., pp. XII+195).—This book contains a revision of 4 lectures given in the Colonial Theater, Boston, Mass., in January, 1905, under the auspices of the education committee of the Twentieth Century Club. Lecture 3 discusses "the school of the future," and states that "A man can be trained to think just as accurately by means even of agricultural subjects as by conventional subjects, provided the agricultural subjects are as well systematized and equally well taught."

Crop demonstrations on state and county farms, C. P. Norgord (Wisconsin Sta. Bul. 208, pp. 3-30, fugs. 13).—The results obtained by the agronomy department in the way of crop demonstrations during the past 2 years, on 20 farms connected with various public, state, and county institutions throughout the State, are given.

Some of the work that is at present under way on most of these farms includes farmers' corn tests, seed selection and breeding, corn planting, alfalfa growing, crop rotation, preparation of seed beds, application of manures, purebred seed growing, forage crop culture, use of flaking mills, treatment of grains for diseases, hemp growing, and weed eradication. The farmers' corn tests have shown that there is a great need for better methods of seed selection and storing. A demonstration picnic is held some time during the summer at each farm where demonstrations are being conducted and has proved to be the best means of bringing the farmers of the neighborhood to view the crops and to hear them explained by a representative of the station.

The transportation companies as factors in agricultural extension, J. Hamilton (U. S. Dept. Agr., Office Expt. Sta. Circ. 112, pp. 14).—Information is given concerning some of the ways in which the transportation companies of
the country have been making an effort to promote agriculture by running educational trains, employing experts to instruct farmers, organizing and conducting demonstration farms, publishing and distributing agricultural bulletins, preparing exhibits, organizing agricultural associations, and cooperating with the agricultural colleges and experiment stations in various other ways. Statistics are quoted showing that the freight tonnage supplied by agriculture in 1909 aggregated 191,351,772 tons and the revenues derived from freight on agricultural products $1,678,625,645.

Conducting a local corn show. B. W. Crossley (Iowa Agr., 11 (1910), No. 2, pp. 10, 11, fig. 1).—Suggestions are given for premiums, for the committee on classification and judging, and for the committee on arrangements.

Proceedings of the fifteenth annual meeting of the American Association of Farmers' Institute Workers, edited by W. H. Beal and J. Hamilton (U. S. Dept. Agr., Office Exp't. Sta's Bul. 238, pp. 89).—This is a detailed report of the proceedings of the meeting held at Washington, D. C., November 14 and 15, 1910, which has been previously noted (E. S. R., 24, p. 95).

**MISCELLANEOUS.**

Annual Report of Florida Station, 1910 (Florida Sta. Rpt. 1910, pp. XCVI—XII, figs. 30).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1910, a list of the publications of the year, a general review of the work of the station during the year, departmental reports, and a list of the periodicals received by the station. Most of the experimental work reported is abstracted elsewhere in this issue.

Annual Report of New Jersey Stations, 1909 (New Jersey Sta's. Rpt. 1909, pp. XVIII—59, pls. 53, figs. 14).—This contains the organization list of the stations, a financial statement for the State Station for the fiscal year ended October 31, 1909, and for the College Station for the fiscal year ended June 30, 1909, a brief report by the director, and departmental reports which are abstracted elsewhere in this issue. A report on the inspection of feeding stuffs has been previously noted (E. S. R., 21, p. 471), as has also one on the inspection of Paris green and lead arsenate (E. S. R., 22, p. 259).

Finances, meteorology, index (Maine Sta. Bul. 186, pp. 393—335+XII).—This contains the organization list of the station; meteorological observations noted on page 418 of this issue; a financial statement for the fiscal year ended June 30, 1910; an index to Bulletins 176 to 186, which together with Official Inspections 19-28, previously noted, collectively constitute the twenty-sixth annual report of the station; a list of the publications issued during the year; and announcements and notes on the work, personnel, and equipment of the station.

Government experimental stations [Holland] (Country Life [London], 29 (1911), No. 751, p. 736, pl. 1).—This is an account of the experiment stations in Holland which are under the control of the government, in particular the station at Hoorn, which is devoted chiefly to investigations relating to dairying.

Fixing standard weights and measures (Nevada Sta. Bul. 77, pp. 11).—This bulletin contains the text of the state law fixing standard weights and measures, the supervision and enforcement of which is placed in the hands of the director of the station as ex officio sealer of weights and measures.
NOTES.

Alabama Canebrake Station.—The State appropriation to the station has been increased from $2,500 to $4,000 per annum. An entirely new board of control has been appointed, no member of which, under a recent law, can succeed himself. The personnel of the new board is as follows: R. K. Poole, O. L. Woodfin, and C. L. Johnston, all of Unisontown, for terms of five, four, and two years, respectively; John C. Webb, of Demopolis, for three years; and Frank I. Derby, of Whitfield, for one year.

F. D. Stevens has resigned as director, this taking effect September 1, and has been succeeded by W. H. Moore.

Idaho University and Station.—F. D. Farrell resigned as director of extension work in south Idaho and superintendent of the southern Idaho substations on July 15 to take up work in the Bureau of Plant Industry of this Department. Walter H. Olin has been appointed director of the extension department and entered upon his duties August 1, with headquarters at Boise.

Iowa College and Station.—H. C. Cosgriff has been appointed field superintendent in the agronomy and soils department of the station to succeed L. W. Forman, who has been appointed instructor in soils. William G. Gaessler has been appointed assistant chemist and L. A. Maynard assistant in chemistry.

Louisiana Stations.—J. M. Jennings and S. Byall, graduates of the Mississippi College, have been appointed assistant chemists at the State Station.

Maine University.—H. G. Bell has resigned as professor of agronomy to accept a commercial position, and has been succeeded by George E. Simmons, formerly associate professor of farm management. W. A. Brown, assistant professor of poultry husbandry, has resigned to become poultry expert for the Canadian Department of Agriculture.

Maryland College and Station.—C. P. Close has resigned as professor of horticulture and horticulturist to accept a position in connection with the botanical investigations of this Department. W. E. Hanger, a 1911 graduate of the Ohio State University, has been appointed assistant agronomist.

Minnesota University and Station.—R. H. Williams has been appointed assistant professor of animal husbandry in the university and assistant animal husbandman in the station.

Missouri University and Station.—A poultry department has been organized for both instruction and experimental work in poultry husbandry and poultry diseases. H. L. Kempster, instructor in poultry husbandry at the Michigan College, has been appointed assistant professor of poultry husbandry, and will be in charge of the department.

The veterinary department is actively engaged in the hog-cholera campaign, sending out over 54,000 doses of serum during the first eight months of 1911. During August alone 15,000 hogs were inoculated and a force of four men is now in the field in the most heavily infected counties. It is believed that at least double the State appropriation of $25,000 for the work is being saved monthly to the farmers of the State.
A new dairy barn is under construction, which it is claimed will be the finest dairy barn in the State. The main structure will be largely of native stone and the two silos connected with it are to be of reinforced concrete. Feed elevators, litter carriers, and other modern equipment are to be installed, and a milk room is to be erected adjoining the barn but completely detached from the stables.

The State Board of Agriculture has offered a $100 scholarship in the short course this winter to the winner of a contest open to farm boys of the State. In this contest complete records of the milk and butter-fat production of at least three cows for the month of September are to be kept, and the award is to be based both on the records themselves and the completeness and accuracy of the reports.

A four-year course for women has been established, leading to the degree of B. S. in Agriculture. This includes much of the home economics course with considerable agricultural training and numerous electives. A short course for girls in home economics is also offered for the first time.

The station is making an extensive exhibit at the county fairs. This exhibit is planned to show in a graphic manner the results of the experiments under way at Columbia and the 18 outlying experimental fields.

Dr. Paul Schweitzer, connected with the institution as professor of chemistry and later of agricultural chemistry from 1872 to 1906 and since that date chemist emeritus, died July 30 at the age of 71 years. He was chemist to the experiment station from its organization and served for a time as director. Dr. Schweitzer was a native of Germany and studied at Göttingen, coming to this country in 1865. He had held positions in the Polytechnic Institute of Philadelphia and the Columbia School of Mines. He received the degree of L.L. D. from the University of Missouri in 1897.

F. H. Demarce, acting agronomist in the station, has resigned to take up commercial work and has been succeeded by J. C. Hackleman as instructor in agronomy. H. G. Lewis has been appointed assistant in the soil survey, L. M. Nelson assistant in agricultural chemistry, and P. M. Brandt assistant in dairy husbandry.

Nebraska University and Station.—J. H. Frandson, for the past four years professor of dairying and dairyman at the Idaho University and Station, has been appointed professor of dairy husbandry in the university and dairyman in the station, and entered upon his duties October 1. Fred M. Hunter, a 1905 graduate of the university and at present superintendent of schools in Norfolk, Nebr., has been appointed principal of the school of agriculture to fill the vacancy caused by the death of Prof. A. E. Davisson, previously noted.

New Hampshire College and Station.—F. Rasmussen, whose resignation as head of the dairy department has been reported, has reconsidered his decision and will remain at this institution. W. L. Slate, jr., assistant in agronomy, has accepted a position as associate professor of agronomy at the University of Maine, entering upon his new duties the last of September.

New Jersey College and Stations.—Plans are being formulated for a two-story entomological building. The first story will be devoted to classroom and laboratory work, and the second to offices, entomological collections, and the use of the station. Work has been begun on the new poultry buildings and greenhouses provided for by the State legislature.

A. W. Blair, of the Florida Station, has been appointed associate chemist in the department of soil chemistry and bacteriology, and R. L. Willis assistant chemist in the fertilizer department. E. W. Stafford has resigned as assistant entomologist and has been succeeded by Raymond S. Patterson. C. J. T. Doryland, instructor in the short courses in agriculture, and E. L. Dickerson, of the
entomological department, have also resigned, the former to accept an assistant professorship at the North Dakota College and the latter an instructorship at the Newark High School.

North Carolina College and Station.—The appointment is announced of J. P. Pillsbury, of the Pennsylvania College and Station, as professor of horticulture in the college and horticulturist in the station, vice F. C. Reimer, beginning September 1. Dr. J. D. Cecil, assistant in anatomy and physiology in the college and animal pathologist in the station, resigned July 1 to take up commercial work.

Oregon Station.—Harry L. Rees, assistant in botany at the University of Missouri, has been appointed research assistant in plant pathology and has entered upon his duties.

Tennessee Station.—The appointment is noted of J. I. Hardy as assistant chemist.

Texas College and Station.—The death on July 26 is noted of Dr. Raymond H. Pond, plant pathologist to the station since 1906. Dr. Pond was born in Kansas March 31, 1875, and received both the bachelor's and master's degrees at the Kansas College. Subsequently he studied at the University of Michigan, from which he received the Ph. D. degree in 1902, and at the New York Botanical Garden and at Bonn and Strassburg. Previous to going to Texas he had held a number of positions, among them that of botanist and pathologist at the Maryland College and Station in 1900–1, professor of botany and pharmacognost and director of the microscopical laboratory at Northwestern University in 1906–7, and biologist of the Municipal Sewage Commission of New York City in 1908–9. He had also served as a special assistant to the United States Fish Commission.

C. H. Alvord has resigned as professor of agriculture and superintendent of the college farm to accept a commercial position.

Utah College and Station.—E. P. Hoff, instructor in zoology and assistant entomologist, has resigned to engage in commercial work, and has been succeeded by M. A. Nelson, a graduate of the college.

Vermont University and Station.—Andrew A. Borland, assistant in dairy husbandry in the Pennsylvania College and Station, has been appointed professor of dairying in the university and dairy husbandman in the station.

Washington College and Station.—Leonard Hegnauer has resigned as professor of agronomy in the college and agronomist in the station to accept the professorship of crop production in the University of Illinois, and has been succeeded by Dr. Paul J. White, assistant professor of farm crops in Cornell University and Station. Other appointments are those of Charles F. Monroe as instructor in animal husbandry in the college and assistant animal husbandman in the station and J. L. Stahl as horticulturist of the Puget sound station.

West Virginia University.—A special horticultural train was operated over the Baltimore & Ohio Railroad through the eastern counties of the State August 7–11. A special feature of the train was the demonstration of improved methods of packing apples and peaches. The home mixing of fertilizer was demonstrated, and alfalfa and forage crops were also discussed.

I. S. Cook, jr., a 1906 graduate of Ohio State University, has been appointed associate professor of agronomy.
EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, Ph. D., Assistant Director.
Assistant Editor: H. L. KNIGHT.

Note.—The price of Experiment Station Record is $1 per volume, and two volumes are issued annually. It may be purchased from the Superintendent of Documents, Washington, D. C., to whom all remittances should be made. The publications of the State experiment stations are distributed from the stations and not from the Department.
A centrifugal method for the determination of humus, A. A. Wells, W. H. Stevenson, and W. F. Coover (Iowa Stu. Bul. 124, pp. 370-384, figs. 4).—Since the official method, as modified by Frear, requires a long time for filtration, and the Mooers-Hampton modification presents some difficulty in the way of preventing losses of humus when the clay is filtered off in a flocculated state and in addition requires a very long time for evaporating the extracts, the authors sought to obtain a new procedure by modification or otherwise. In no case was a satisfactory result obtained by the filtration method.

The authors devised a centrifugal method which utilizes a Gallenkamp centrifuge, containing in its drum a platinum cup for holding the soil. The method is as follows:

"After washing free from chlorids, the soil is transferred to a 1-liter shaking bottle with 500 cc. of a 4 per cent ammonia solution, using a glass rod to loosen the soil. . . . The flask is then stoppered with a rubber stopper, placed in the shaking apparatus, [which is described], and shaken at the rate of 50 revolutions per minute for 3 hours. At the end of this time the bottles are removed and the contents allowed to settle for 10 minutes. . . . About 350 cc. of the solution is then decanted through a funnel into the centrifuge bowl, the top clamped in place, and the solution whirled for 10 minutes. By means of a thumb screw a part of the solution is drawn off through the glass tube while the machine is still at full speed. The first 10 cc. is discarded and then about 70 cc. of the solution is collected. This amount is readily caught in a small beaker, which should be covered at once with a cover glass to prevent loss by evaporation.

"Fifty cc. of the solution, which represents 1 gm. of soil, is drawn off with a pipette, placed in a weighed porcelain dish, and evaporated to dryness on a steam bath. The dish is then dried to constant weight in an oven at 110° C., and the weight recorded. The contents of the dish are then ignited in a muffle furnace and weighed again after cooling to room temperature. The loss in weight upon ignition represents the weight of the humus, and the increase of the last weighing over the empty dish represents the weight of the ash."

With this method the time required for determining the humus is reduced to one-third of that usually employed for the official method.

the detection of adulteration are described and examinations of a number of samples of different kinds of superphosphate with reference to adulteration are reported and discussed.

A modified method for estimating sugar in sugar beets, A. HERZFELD (Ztschr. Ver. Deutsch. Zuckerindust., n. ser., 46 (1909), II, pp. 627-633, figs. 3).—This is a simplification of the Sachs-Le Docte method, and is carried out as follows:

Twenty-six gm. of the beet paste is placed in a special metal beaker, an illustration of which is given, and 177 cc. of a solution consisting of 5 parts of lead acetate solution (German Pharmacopoea) and 95 parts of water is added. The beaker is then stoppered with a cork covered with tinfoil, and the mixture shaken thoroughly, filtered, and polarized. If a coarse paste is being examined, the mass in the beaker is placed in a water bath at 75 to 80° C. for 30 minutes, then cooled, filtered, and polarized.

The authors conclude from their work that the new Herzfeld method must be considered, for the present at least, the most accurate and convenient one for laboratories making a great many sugar determinations in beets. They criticize, however, the tinfoil cork stopper.

Calorimetry of Argentina butter, E. H. and L. H. Ducloux (Trab. 4, Cong. Cient. Santiago de Chile, 4 (1908-9), pp. 151-160).—Analytical constants of butter are reported. The authors find that determining the heat of combustion is of value in order to supplement the saponification, the Reichert-Meissi number, and the index of refraction for detecting adulterated butter.

A method for the separation of the seven permitted coal tar colors when occurring in mixtures, T. M. Price (U. S. Dept. Agr., Bur. Anim. Indus. Circ. 189, pp. 7).—According to the author, no analytical scheme seems to exist in the literature for separating coal tar colors when present in a mixture containing one or more of the seven coal tar colors permitted by the regulations governing meat inspection. A method is therefore proposed which is based on the solubility and insolubility of the colors in the following reagents: A supersaturated solution of ammonium sulphate, a supersaturated solution of sodium chlorid, calcium chlorid solution (25 per cent), dilute ammonia (1:100), dilute acetic acid (5 per cent), stannous chlorid solution, acetone, alcohol (95 per cent), amyl alcohol, acetic ether (ethyl acetate), ether, sulphuric (ethyl) ether, and hydrogen peroxid (3 per cent).

Analysis of sweetened condensed milk, A. Backe, A. Wiborg, and E. Röer (Analyst, 36 (1911), No. 421, pp. 138-141).—The authors point out that in tins of condensed milk which have stood for a time the fat has a tendency to rise to the top and the lactose and saccharose to crystallize out on the bottom. It is also possible for these separations to take place during the process of manufacture. These facts often cause considerable error in the analysis of condensed milks. To illustrate this they present the results of zonal analyses of canned condensed milk.

The detection of benzoic acid in meats and fats, K. Fischner and O. Grünert (Ztschr. Untersuch. Nahr. u. Genussmittel, 17 (1909), No. 12, pp. 721-733).—The method employed is as follows:

The material is finely minced, 50 gm. weighed out and 100 cc. of 50 per cent alcohol added. This is acidified with dilute sulphuric acid and allowed to stand for 30 minutes, with frequent agitation. The mixture is then passed through a piece of gauze cloth and the residue expressed to remove the re-
minder of the liquid; the extract made alkaline and heated on the water bath until all the alcohol is driven off, then made up to a bulk of 50 cc., mixed with 5 gm. sodium chlorid, acidified with dilute sulphuric acid, heated to the boiling point, cooled, and filtered, the filtrate shaken with ether, and finally washed several times with water. The ether extract is evaporated to dryness at a low heat. The extract thus obtained can be used for the tests, or it may be converted into salicylic acid by the procedure recommended in the article.

Comparative tests were made with different methods for detecting the benzoic acid. For the test with ferric chlorid the residue was dissolved in water containing ammonia, the solution evaporated to 1 cc., and 1 drop of 1 per cent ferric chlorid solution added. The author was able to detect 0.02 per cent of benzoic acid in smoked and fresh flesh and from 0.005 to 0.01 per cent in fats. Rohrig's ethyl-ester odor test was sensitive to 0.02 per cent benzoic acid in fresh meat and 0.01 per cent in fats, but no result was obtained with smoked meat. Brevan's test gave negative results. By converting the benzoic acid into benzaldehyde, 0.04 per cent was detected in fresh meat, but with smoked meat the result was negative. With lard, 0.01 per cent could be found, while the results with margarin were variable, and with butter always negative. Mohler's test, which is based on the conversion of the benzoic acid into the red-brown colored ammonium compound of amido-nitro or the diamido-benzoic acid, also yielded negative results.

Detection of benzoic acid in meats and fats, K. Fischer and O. Gruxert (Ztschr. Untersuch. Nahr. u. Genuesmatl., 29 (1910), No. 9, pp. 589-583).—The authors investigated the von der Heide and Jakob modification (E. S. R., 23, p. 12) of Mohler's method, which avoids the high temperature recommended by Mohler, and found that it could also be employed for detecting benzoic acid in butter, lard, and fresh, pickled, and smoked meats.

The authors have also modified their own method, which is given in the abstract above, for extracting the benzoic acid from butter and fats, and now proceed as follows: Fifty gm. of the butter are placed in a 300 cc. Erlenmeyer flask with 150 cc. of a 1 per cent sodium bicarbonate solution, boiling for 5 minutes, and shaking during the process. The hot fluid is transferred to a separatory funnel, and the aqueous solution, which now contains the benzoic acid, is separated from the fat. The cloudy alkaline solution is then neutralized with half-normal sulphuric acid, using methyl orange as the indicator. In order to obtain a clear solution quickly, 10 cc. of Fehling's copper sulphate solution and 10 cc. of potassium hydrate (containing 31.15 gm. potassium hydrate per liter) are added. After the precipitate has settled the supernatant fluid must possess a slightly acid or neutral reaction. The solution is filtered, the clear filtrate acidified with dilute sulphuric acid, and the benzoic acid extracted with ether. The ether extract is washed several times with water and the ether evaporated on the water bath with the aid of a current of air. On detecting the benzoic acid it is converted into salicylic acid, according to the method recommended by these authors.

The authors have also investigated the Jonescu method (E. S. R., 21, p. 523), but found it to be less valuable than the modified Mohler method.

Estimation of tartaric acid, A. Hecke (Ztschr. Analyl. Chem., 50 (1911), No. 1, pp. 12-21; abs. in Analyst, 36 (1911), No. 421, p. 148).—In the hands of some chemists the Goldenberg method, which is the method usually employed,

sometimes yields results which vary from the correct figure not less than from
0.4 to 0.5 per cent. This is due to the fact that potassium bitartrate is not
altogether insoluble in alcohol, and also to the action of the neutral potassium
tartrate on freshly precipitated calcium carbonate.

The author points out that the error due to the first cause may be eliminated
by treating the potassium bitartrate with standard caustic alkali, just as though
it were a sample of argol, instead of titrating it directly. He also points out
that where a high lime content is present the amount of potassium carbonate
specified by Goldenberg is insufficient, and is liable to indicate very much less
tartaric acid than is present in the sample. Other errors may be introduced
by mechanical losses during evaporation.

Estimation of total tartaric acid, A. Heczko (Ztschr. Analyt. Chem., 50
(1911), No. 2, pp. 73–82; abs. in Analyst, 36 (1911), No. 421, pp. 148, 149).—
An investigation of the Moszczenski method \(^a\) showed that with pure tartrates
the results are correct, but with crude tartar they are from 1 to 2 per cent too
high. The method is, however, more rapid than the Goldenberg process.

Methods for estimating ethyl alcohol quantitatively, A. Baudrexel (Deut.
Essigindus., 15 (1911), No. 9, pp. 67–69).—A discussion in regard to the existing
methods for the quantitative determination of alcohol.

Hydrolysis of casein, T. B. Osborne and H. H. Guest (Jour. Biol. Chem., 9
(1911), No. 3–4, pp. 333–353).—On the basis of a summary of data, including
the investigations reported and earlier work from Osborne’s laboratory, it is
pointed out that there is a relatively large discrepancy between the sum of the
nitrogen of known decomposition products of casein and the total theoretical
amount. Possible explanations are suggested.

The paper as a whole is an important contribution to the chemistry of casein.

The occurrence of sucrose in grapes, W. B. Alwood (Jour. Indus. and Engin.
Chem., 2 (1910), No. 11, pp. 481, 482).—The author and his coworkers \(^b\) found
sucrose in several varieties of grapes belonging to the species commonly cul-
vatted in the United States, but more especially in a new seedling grape dis-
covered growing near Sandusky, Ohio, which was until then unknown to horti-
cultural literature.

"The known varieties in which sucrose was found to occur are Hayes,
Pocklington, and Worden. These showed sucrose in quantities varying from
4.49 to 5.66 gm. per 100 cc. of juice. The new seedling, however, showed sucrose
varying at different dates from 7.66 to 9.73 gm. per 100 cc. of juice, with a total
sugar content varying from 15.93 to 19.52 gm. per 100 cc. of juice. . . . [The
author and his coworkers] have now examined in the laboratory a large series
of samples of practically all the wine and table grapes grown in the Eastern
States, and in no case other than mentioned above have [they] found sucrose
in appreciable quantity."

The occurrence of sucrose (cane sugar) in unfermented grape juice (Pure
Products, 7 (1911), No. 8, pp. 331, 335).—Substantially noted above.

pp. 24).—In addition to reporting what is noted in the abstract above, the
author in this bulletin gives the results of examining the Illinois City, Nectar,
Norton, Catawba, and Montefiore varieties of grapes for sucrose. Sucrose was
present in appreciable quantities in the first three varieties and in the last
two, in amounts ranging from 0.04 to 0.4 per cent, which, according to the
author, does not point positively toward the presence of sucrose.

Comparing the results obtained by examining the seedling grape (see abstract
above) from the time it became edible until it was overripe during 1909 with

those obtained in 1910 showed that "the total sugar content in the fresh fruit varied about 3 per cent in the first year and about 5 per cent in the second year. The ratio of reducing sugar to sucrose content varied from 1:0.80 to 1:1.04 in 1909 and from 1:1 to 1:1.19 in 1910, thus showing a fairly constant proportion between these two forms of sugar. The total acid content decreased about one-third in each year during the period the variety was under examination."

Some further work conducted during 1909 and 1910 in regard to the sugar and acid content of the grape, sampled at different intervals during ripening and at full maturity, are also reported. During 1909 the grapes examined were of the Catawba, Montefiore, and Norton varieties, and the seedling noted above. For the Catawba grapes it was noted that an increase in sugar and a decrease in acid took place. "The Montefiore grapes showed an insignificant loss of sugar for the period as a whole and a very appreciable loss of acid. In the case of the Norton the sugar remained practically the same, but the acid was greatly decreased. . . . The seedling showed a decided gain in sugar and an important loss in acid, considering the entire period, but there was a phenomenal gain in sugar during the second period and an equal loss during the next one. This must be credited to the uneven growth and ripening of this seedling, normal samples being hard to obtain during the fall of 1909."

During 1910 the varieties Brighton, Catawba, Clinton, Concord, Delaware, Ives, Norton, Pocklington, and Worden, and the seedling were examined. The period for sampling in this investigation was much longer than that of 1909.

"For Catawba the total sugar does not in any sample reach the average of the general crop of that section, but the acid is about at the minimum for this variety on the date when the last sample was taken. At that time the sugar had apparently decreased, but the difference was too slight to be considered, in view of the difficulty of taking two samples of grapes from the same lot which do not show similar differences in composition. This variety in 1910 was high in sugar wherever the growth conditions were good. The fruit as sampled more than doubled in sugar after the berries began to color and lost more than half of the acid content shown in the first sample. The very decided loss of acid even for the last 7 days, amounting to 0.481 per cent, is most important, although the sugar increased only 1.16 per cent. The ratio of increase of sugar to loss of acid is very low for this variety. The observations with this variety were not continued long enough to be conclusive, according to the author.

"Clinton was sampled for a longer period than any other variety. . . . The analyses show that there was some increase of sugar up to the last sample, loss of acid is not so important as for Catawba, but the gain in sugar in proportion to the loss of acid is greater.

"The Concord samples were in remarkably good condition at the last analyses. While neither the gain of sugar nor the loss of acid is remarkable in total amount, yet the results show a great improvement in the fruit as sampled for this study as compared with the samples harvested for the vintage. . . . The proportional increase of sugar to loss of acid for this variety is above that of any of the strictly wine grapes.

"The data for Delaware show that . . . the rise in sugar during the 26-day period when this variety was sampled was not so great in proportion to the total as was found in the Catawba, Clinton, or Norton, but the drop of over one-half in total acid is of the greatest significance, and the proportional increase of sugar to acid lost is greater than in the other varieties of strictly wine grapes mentioned.
Ives was uniformly poor in quality in 1910, but the data as to acid decrease and proportional sugar increase are important.

Norton shows a consistent and steady rise in sugar and a notable decrease in acid during the period of sampling. Yet in the maximum sample the sugar was lower and the acid higher than is usual for this variety when grown in the most suitable environment. Evidently this grape requires a longer growing season than is usual at Sandusky. The acid-sugar ratio, however, greatly exceeds the figure for Catawba, and the percentage increase of sugar is the greatest recorded for any variety.

Pocklington is of too little consequence as a vintage fruit to warrant an extended study of the character here undertaken.

The Seedling, whose peculiar composition led to the sucrose investigation, was also included. The commercial importance of this grape in its present development is slight, but the remarkable fact that its ratio of loss of acid to increase of sugar is 1:23.6 is a most notable item in the chemistry of the grape. If . . . accompanied by greater vigor, a valuable product should result.

Worden is so much like Concord that chemically it is not necessary to study the two varieties in an investigation of this nature. . . . It is, however, notable that this variety when fully ripe is rich in sugar, with a proper proportion of acid.

A chemical investigation of the oil of chenopodium. E. K. Nelson (U. S. Dept. Agr., Bur. Chem. Circ. 73, pp. 10).—Four authentic samples of Maryland chenopodium oils (3 from steam stills and 1 from an old-fashioned pot still) were submitted to a chemical and physical analysis. The results on examining the steam-still oils were as follows: Specific gravity at 25° C, 0.955 to 0.970; \( \eta_D \) at 25° C, 1.4723 to 1.4726; \( a_P \) at 25° C, —5.4° to —8.8°, and the solubility in 70 per cent alcohol, 1:3 to 1:7. For the pot-still oil the figures were: Specific gravity at 25° C, 0.9584; \( \eta_D \) at 25° C, 1.4725; \( a_P \) at 25° C, —6.3°, and solubility in 70 per cent alcohol 1:6.

In addition to the above the author examined a sample of chenopodium oil obtained on the open market, with the following results: Specific gravity at 25° C, 0.9694; \( \eta_D \) at 20° C, 1.4780; \( a_P \) at 20° C, —0.35°; solubility in 70 per cent alcohol, 1:3; acid number, 0; ester number, 5. On fractionating this oil at 8 mm. about 15 per cent of hydrocarbon was obtained, which, when distilled over sodium, yielded a pleasant smelling liquid having a boiling point of 176° C. (766 mm.), a specific gravity of 0.8513 at 20° C, \( \eta_D \) at 20° C, 1.4828, and \( a_P \) at 20° C, —18.5°. Cymene was noted in the fraction. The fraction coming over before ascaridol contained at least 4 per cent of dextro camphor, which accounts for the low rotation of the sample.

Some tests which were also made to determine the nature of ascaridol seemed to indicate, according to the author, that it is an organic peroxid. Formulas are presented which show a relationship to oxythymo quinon.

Lime-sulphur wash. R. Harcourt (Ann. Rpt. Ontario Agr. Col. and Exp. Farm, 36 (1910), pp. 100–102).—This is a study of the effect of adding freshly-slaked and air-slaked lime, and also lead arsenate, Paris green, and calcium arsenite, to lime-sulphur sprays.

The results for lime show that while there is a breaking down of the polysulphides, this is hardly in such an amount as to condemn the addition of lime to lime-sulphur sprays. Air-slaked lime was less destructive to the wash than freshly-slacked lime. The author, however, recommends the latter because it is not so granular and does not settle rapidly.

The results obtained for arsenicals correspond to the findings previously reported (E. S. R., 23, p. 60), and show that “Paris green reduces the strength of the wash nearly 50 per cent, whereas the reduction caused by the other two
is not sufficiently great that their use could be condemned. Lead arsenate does not affect the strength of the wash quite so much as calcium arsenite, but it is much more expensive, and a choice between the two will depend upon which will be the safer to apply to foliage."

The utilization of crop plants in paper making, C. J. Brand (U. S. Dept. Agr., Yearbook 1910, pp. 329–340, figs. 3).—This is a discussion and report of work carried on with cornstalks, broom corn, hemp stalks, saccharin and non-saccharin sorghum stalks, cotton stalks, flax and rice straw, bagasse, tules, hemp wastes, cotton hull fiber, Eriocampus macroura (a southwestern grass, the tops of which are a by-product from the root-brush industry), Arundo, Arundinaria, Enhalia, and several other plants with regard to the possibility of utilizing them as a source of raw material for paper making.

As the result of tests and observations, the author believes that "a point may soon be reached where crop by-products can be made into pulp and paper at a profit to both the farmer and the manufacturer. There does not seem to be any reasonable hope at the present time of producing paper stock from crop wastes that will be cheap enough to use for printing newspapers. This is due chiefly to two causes—the low cost at which such paper can be produced from ground wood and the striking adaptability of ground wood pulp to the newspaper printing industry. . . . Wood will probably be used for making news paper long after other materials have acquired importance in many branches of the chemical pulp industry. . . . While the conservation of only a few of the by-products of the farms yielding paper fiber can be accomplished profitably in the near future and only a few plants promise to be money-makers immediately if grown solely for paper production, it seems very probable that raw products now scarcely considered may in a few years play an important part in the paper and pulp industry."

Manufacture of potato spirit in Germany, R. P. Skinner (Daily Cons. and Trade Rpts. [U. S.], 13 (1910), No. 148, pp. 1167–1169).—After discussing the classification and the derivation of alcohol, the author details the processes for preparing alcohol from potatoes, as practiced in Germany. Statistics in regard to prices and production are included.

Yearbook of chemistry, edited by R. Meyer et al. (Jahrb. Chem., 19 (1909), pp. XII–607).—This is a report of the more important progress made in the field of pure and applied chemistry for the year 1909.

METEOROLOGY—WATER.

[The organization of agricultural meteorology], L. Dor (Rapport Présenté au Comité Permanent sur la Question N. 6 du Programme de L'Assemblée Générale de 1911 Concernant la Météorologie Agricole. Rome: Inst. Internat. Agr., 1911, pp. 61).—This is a report to the International Institute of Agriculture setting forth the importance of organizing systematic international observations in agricultural meteorology and proposing a plan for such organization.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. Ostrander, C. M. Daxion, and R. N. Hallowell (Massachusetts Sta. Mtcl. Buls. 269, 270, pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during May and June, 1911. The data are briefly discussed in general notes on the weather of each month.

The weather of the past agricultural year, F. J. Brodie (Jour. Roy. Agr. Soc. England, 71 (1910), pp. 358-363).—This is a brief account of weather conditions in the United Kingdom during 1910, including tabulated data on rainfall, temperature, and sunshine.

Meteorological observations, 1901-1910, T. Marr (Meded. Proefstat. Java-Suikerindust., 1911, No. 8, pp. 91-142, fig. 1, chart 1).—This article describes the equipment used at the meteorological station at Passoerocan. Java, and summarizes the results of observations at the station from 1901 to 1910, inclusive, on pressure, temperature, sunshine, evaporation, cloudiness, rainfall, wind velocity, and temperature of the soil for different depths.

Climate of the coast and alluvial districts of Belgium, J. Massart (Rec. Inst. Bot, Léo Errera Bruxelles, 7 (1908), pp. 298-355, figs. 3).—The climatic conditions of these districts of Belgium are discussed in their relation to the distribution and adaptation of plants.

Mountain snowfall observations and evaporation investigations in the United States, F. H. Bigelow (U. S. Dept. Agr. Yearbook 1910, pp. 307-412, pl. 1).—This article points out the scientific and practical importance of observations which are being made by the Weather Bureau on the snowfall in western mountain ranges in relation to water supply and on evaporation from lakes and storage reservoirs, particularly at Reno, Nev., and on Salton Sea. The methods employed in this work are briefly described.

A note on the evaporation gradient in a woodlot, M. G. Dickey (Ohio Nat., 11 (1911), No. 7, pp. 337-349).—Observations on the evaporation at different heights from the ground in a woodlot are reported, showing "that the greatest evaporation has occurred in every case at the 6-foot level, pointing to a decrease in relative humidity from below upward. The 33-foot reading exhibits a modification of this relation, which is due to the moisture given off in the transpiration of the leaves in the forest crown." The data do not show a uniform increase of the saturation deficiency from the lowest level upward.

Depositional phases of eolian under the stimulus of aridity, C. R. Keyes (Abs. in Science, n. ser., 33 (1911), No. 362, p. 29).—The following abstract is here given of a paper read before the Iowa Academy of Science:

"It is now a question whether wind-scour under the stimulus of a typically arid climate is not actually the most potent and persistent of all erosive agencies. Under favorable conditions its general efficiency must greatly exceed that
of stream action in normally moist lands. At any rate, errosionally, its world's work is probably surpassed neither by that of hydrosion nor by that of glaciation.

Nitrogen in rain and snow, N. Knight (Abs. in Science, n. ser., 33 (1911), No. 862, p. 28).—This is an abstract of a paper read before the Iowa Academy of Science, as follows:

"Seventeen samples of rain and snow were collected on the college campus at Mount Vernon, Iowa, during nine months of the year 1909-10. The nitrogen in the free and albuminoid ammonia and in the nitrates and nitrites was determined. Comparisons were made of the relative amounts of nitrogen precipitated with the rain and snow. According to the experiments, each acre would receive in the nine months between 13 and 14 pounds of nitrogen from the rains and snows."

Cannonading against hail, J. M. Guillou (Jour. Agr. Prat., n. ser., 21 (1911), No. 14, p. 4/2).—This is a brief account of organized efforts in France to prevent hailstorms by cannonading.

The climatic requirements for fruit culture, P. Holdefleiss (Ber. Landw. Reichsant. Innern [Germany], 1910, No. 17, pp. 78-86).—This article discusses the moisture, temperature, and sunshine conditions best suited to fruit culture.

Rainfall distribution over the growing period of wheat, A. J. Perkins and W. J. Spafford (Jour. Dept. Agr. So. Aust., 14 (1911), No. 19, pp. 964-966).—The distribution of rainfall and the yield of wheat from 1905 to 1910 on the experimental field of the Roseworthy Agricultural College, South Australia, are shown in the following table:

<table>
<thead>
<tr>
<th>Year</th>
<th>Seeding and winter rain, May-July</th>
<th>Spring rain, April-August</th>
<th>Autumn rain, September-October</th>
<th>Total rainfall, Inches</th>
<th>Rain without influence, Inches</th>
<th>Average grain yield of plats, Bu.</th>
<th>Rain on following year, August-October</th>

</table>

The author concludes from his observations that the ultimate success of the wheat harvest depends primarily on the existence of normal conditions at seeding time followed by good growing winter weather. When the rainfall during this period falls decidedly below the 6.35 in. shown in the table as the mean of 27 years the ultimate yield is likely to suffer.

The agricultural duty of water, W. J. McGee (U. S. Dept. Agr. Yearbook 1910, pp. 169-176).—The author discusses the relation of the soil to soil water, soil-plant circulation, the ratio of crop to water supply, and the duty of water, and finally reaches the conclusion that "in a broad way it may be said that the final duty of water is to sustain a human life a year for each 5 acre-feet used effectivly in agriculture."

Daily river stages at river gauge stations on the principal rivers of the United States. Part X, For the years 1909 and 1910, H. C. Frankenfield (U. S. Dept. Agr., Weather Bur. Doc. 453, pp. 397).—This is the tenth of the
series of reports on "river gauge readings, the publication of which was begun by the Signal Service and has been continued by the Weather Bureau. . . . The tabulated gauge readings are accompanied by a statement which includes the locations of the stations, descriptions of gauges and bench marks, heights of flood stages, low-water and flood marks, and other data, for the various river stations whose gauge readings are included in the tables."

**Agricultural and industrial hydrology of Argentina, E. H. Ducoux** (Trab. 4. Cong. Cient. Santiago de Chile, 4 (1908-9), pp. 5-38+[21]).—This report deals with the surface and underground waters of different districts of Argentina and gives data regarding the distribution, quantity, and composition of the waters.

**American mineral waters: The New England States, W. W. Skinner and G. W. Stiles, Jr.** (U. S. Dept. Agr., Bur. Chem. Bul. 139, pp. 111, figs. 2).—This is the first of a proposed series of bulletins on American mineral waters. See also a previous note (E. S. R., 17, p. 641). The bulletin defines natural and mineral waters, discusses the origin of ground waters and the chemical and physical agencies affecting their composition, and describes methods of collection and analysis, stating results, and classifying and naming waters.

The methods of bacteriological examination followed by the Bureau of Chemistry are described in detail. Analyses of 5 waters, from Connecticut, 8 from Maine, 13 from Massachusetts, 6 from New Hampshire, 3 from Rhode Island, and 3 from Vermont are given. The springs are described and the quality of the water as shown by analysis is indicated. The advertised analysis, when available, is given in each case for comparative purposes.

**Farm well water, R. Harcourt** (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 30 (1910), pp. 79-81).—Of 28 samples of farm well water of which analyses are here reported only 4 were considered safe for drinking purposes.

**Pond fertilizing experiments, Kuhnert** (Laude. Weinbl. Schles. Holst., 61 (1911), No. 25, pp. 174-178).—A brief account is here given of a series of experiments during 1910 with Thomas slag, nitrate of soda, kainit, lime, and manure to test this method of increasing the supply of food in fish ponds.

Such use of fertilizers was found as a rule to give a profit in increased amount of fish products. The addition of nitrate of soda to Thomas slag and kainit was found to be especially profitable in increasing the growth of water plants suitable for food for fish. Liming also gave good results. The use of manure was found to be beneficial when employed with care, but as a rule commercial fertilizers proved to be the most suitable for the purpose.

**On the decomposition of water by ultraviolet light, A. Tian** (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 15, pp. 1012-1014).—The experiments here reported indicate that under the action of light from a mercury vapor lamp in quartz, water is decomposed into hydrogen and hydrogen peroxide with ultimate evolution of oxygen. Eventually, therefore, the action of the light is identical with that of electrolysis as far as the gases evolved are concerned.

**Home waterworks, C. J. Lynde** (New York, 1911, pp. 211+270, figs. 106).—This is one of the series entitled The Young Farmer's Practical Library, edited by E. Ingersoll, and is described in the subtitle as a manual of water supply in country homes. It deals in a concise, simple manner with the value of water indoors; first steps in kitchen equipment; underground water, wells, springs, rivers, lakes, and cisterns as sources of water supply; the construction and operation of pumps; gravity and pneumatic tanks; and plumbing and sewage disposal. A list of firms dealing in water supply and plumbing materials is appended.

**The protection of water supplies, H. C. H. Shenton** (Supplyor, 39 (1911), Nos. 1008, pp. 698-701; 1009, pp. 732, 733).—The author attempts to show in this
article that it is impossible under present conditions to agree upon any standard, "conformation with which shall prove that water is incapable of producing disease in a greater or less degree." He urges the fixing of a standard "which shall prove that the water is free from given definite organisms believed to be harmful."

Septic tanks for sewage on country places, E. McCulloch (Concrete [Detroit, Mich.], 11 (1911), No. 6, pp. 37, 38, figs. 2).—In view of the increasing use of septic tanks for rural homes, this article describes tanks of simple construction for this purpose, particularly the use of concrete in such construction.

**SOILS—FERTILIZERS.**

Alkali soils, C. Willis and J. V. Borr (South Dakota Sta. Bul. 126, pp. 75-93, map 1).—This bulletin reports the results of determinations of soluble salts, carbonates, and organic matter of different soil types of South Dakota. It is stated that "alkali is found to a greater or less extent over the entire State, however there are certain areas where the extent of the injury is greater than in others. Some of the soils did not contain a large amount of soluble salts. The injury to the growing crops in such case is due largely to excessive moisture or poor drainage."

Counteracting evaporation by cultivation and mulching to prevent the accumulation of the salts at the surface, and treatment with gypsum, where large amounts of carbonates occur, were found to give temporary relief. "However, since many of these soils are found in depressions where there is an excess of water in certain periods of the year, and since the salts are very soluble it necessarily follows that they may easily be carried away in solution. Tile drainage will therefore afford permanent relief. Flooding an irrigated section will wash the salts deeper into the subsoil where it loses its harmful effects. Analyses of drainage waters in various sections have shown that they carried large quantities of salts in solution. Of course surface drainage will also greatly aid, yet it is not as immediate as tiling."

Alkali lands, their utilization and improvement, N. M. Tulaikov (Solontsy, Ikh Izpol'zovanie i Ucheshchest', St. Petersburg: Gort., 1910, pp. 188, figs. 10).—The preface states that this is a report by the author to the department of agriculture of Russia which had sent him to the United States to study the utilization of alkali soils. He spent 18 months in this country, and describes at length all the instances of improving alkali lands which he saw. He also reviews the more important part of the American literature on alkali lands, but does not consider the literature of other countries. His observations are summarized under the following headings: Origin and distribution of alkalis, effect on vegetation, tolerance of plants to alkali, utilization and methods of improving alkali soils, and use of salt water for irrigation.

Soils: Their composition, requirements, and possibilities, C. A. Mooers (Bian. Rpt. Tenn. Dept. Agr., 1909–10, pp. 274–283).—This article deals particularly with the use of lime on different types of Tennessee soil.

The soils of Washington, R. W. Thatcher (Washington Sta. Popular Bul. 34, pp. 4).—This discusses in a popular way what chemical analysis of soils shows, and gives tables showing the average composition of typical Washington soils as well as the amounts of plant food removed from the soil by different crops.

The soils of the coast and alluvial districts of Belgium, J. Massart (Rec. Inst. Bot. Léo Errvra Bruxelles, 7 (1908), pp. 303–344; Sup., 1910, maps 5–9).—The soil conditions of these districts of Belgium are discussed in their relation
to the distribution and adaptation of plants. The article is illustrated with detailed soil maps of the districts.

Soils of Roumania (Rev. Sci. [Paris], 39 (1911), 1, No. 16, pp. 503, 504).

This article, which refers to a continuation of studies of soils of Roumania by Murgoci (F. S. R., 23, p. 315), is based upon a geological soil map published by the Geological Institute of Bucharest. It gives the results of mechanical and chemical analyses of different steppe, forest, residuary, and alluvial soils of the region, as well as of studies of their distribution and agricultural value. Particular attention is called to variations in the humus content of the soils. In the chernozem soils east of Moldavia and Muntenia the humus content was from 4 to 6 per cent, in the chestnut-colored soils of the southeast 4 per cent, in the yellow or light-brown soils along the Danube 2 per cent, and in the cultivated steppe soils it was very low.

Surrounding Bucharest and central Moldavia there occurs a ferruginous soil with 2 per cent humus. It is reported to contain a sort of hardpan (artstein) stratum of ferromanganese concretions from 10 to 15 cm. (3.94 to 5.91 in.) below the surface.

The manganese content of Italian soils, A. Contino (Staz. Sper. Agr. Ital., 44 (1911), No. 1, pp. 51-55; abs. in Chem. Zentralbl., 1911, I, No. 18, p. 1371).—The literature relating to the occurrence of manganese in the soils and ash of plants is reviewed and determinations of manganese in a large number of Italian soils are reported. The method used in the determination is described. The amount of manganese found (calculated as MnO) varied from 0.03 to 0.48 per cent, with an average of 0.17 per cent.

Soil conditions of German East Africa, V. Lommel (Pflanzer, 7 (1911), No. 4, pp. 221-227).—In this article the author discusses the origin, extent, and importance of the different soil types of this region, which are classed as sands, red loam, volcanic soils, and alluvial soils.

Soils of Java, E. C. J. Moir (Veysmannia, 20 (1909), Nos. 8, pp. 486-490; 10, pp. 621-631; 11, pp. 679-686; 12, pp. 757-772; 21 (1910), Nos. 2, pp. 79-91; 4-5, pp. 235-250; 6, pp. 335-364; 9, pp. 578-595; 10, pp. 638-654; 11, pp. 791-792; 12, pp. 747-752).—The work here reported deals with the classification of Java soils, based on a study of the parent rock, climate, and weathering processes. It includes under residuary types the red laterite, yellow laterite, light, dark brown, and alkali soils, and under secondary or transported types soils formed by rivers, seas, and wind.

From the observations the following relations between climatic conditions and soil types were noted: Low countries having hot climates, much sunshine, and wet seasons give rise to red laterite soils, whereas countries with similar climates and amount of sunshine but with alternating wet and dry seasons form dark soils. With continued dry seasons alkali soils are formed.

Rugged countries with cloudy, moderately warm, and wet conditions give rise to the yellow laterite soils, whereas countries with the same cloudy conditions and temperature but with alternating wet and dry seasons form dark brown soils. High rugged regions where cool and wet conditions prevail give rise to a soil consisting of a white weathered mass covered with a dark humus layer.

Two compounds isolated from peat soils, C. S. Robinson (Jour. Amer. Chem. Soc., 33 (1911), No. 4, pp. 563-568; abs. in Jour. Chem. Soc. [London], 100 (1911), No. 583, 11, p. 431).—The isolation of leucin and isoleucin from peat soils is reported.

Soil formation and the importance of geological-agronomical maps for fruit culture, Lienau (Ber. Landw. Reichsamt die Inern [Germany], 1910, No. 17, pp. 37-54).—This is a lecture delivered before the German Pomological
Society in which the author discusses the influence of the chemical composition, humus content, and physical properties of the soil on the character of its vegetation. Particular attention is given to the geological formation of different rocks and their subsequent decomposition and soil formation through the action of weathering agents, with special reference to the soils of northern Germany.

The author emphasizes the fact that it is exceedingly difficult, or even impossible, to draw definite conclusions regarding the final soil product from a knowledge of the parent rock alone. The position is therefore taken that geological agronomical maps are of great practical importance in fruit growing as well as in all kinds of farming in that they deal not only with the geological aspect of the soil but also with its physical and chemical properties and plant adaptations.

Some of the more important soil maps applicable to Germany are briefly noted.

The mechanical analysis of arid soils, W. Beam (Cairo Sci. Jour., 5 (1911), No. 56, pp. 107-119, fig. 1).—The author made a study of different methods of mechanical analysis used by other investigators with a view to adapting them to the analysis of arid soils.

The method advocated by the Bureau of Soils of this Department appeared to be the most promising; but trials with arid soils showed that it failed, as did most of the other methods, to separate a very considerable portion of the clay, which goes to swell the silt and other fractions.

Further tests were made of the clay content of arid soils as affected by length of time of agitation, adding varying amounts of sodium carbonate, with and without heat, and the height of the liquid in subsidence, together with a study of the size of clay particles, the silt content, and the classification of soil particles.

The method of mechanical analysis of soils finally adopted and used with success at the Khartum laboratories is described. The essential points of this method are the use of from \( \frac{1}{4} \) to \( \frac{1}{2} \) gm. of sodium carbonate in 100 cc. of water and the use of a brush in puddling. Boiling with dilute sodium carbonate without the use of the brush not only required double the number of decantations to effect a separation of the clay, "but the sum total of clay removed was 51.5 per cent as against 54 per cent by the use of the brush."

Separation of the clay by means of the centrifugal machine was found to be more rapid, but required much more of the operator's attention.

The author calls attention to the fact that although the proposed method is recommended especially for arid soils, "it is equally suitable for those of humid regions. Further, it is held that a method of this kind should invariably be used, since otherwise the comparison of humid with arid soils becomes impossible. It must be recollected also that the treatment by acid not only results at times in the complete solution of the larger particles, but invariably in the extraction of material from the finer constituents, so that as a method of 'mechanical' analysis it can not but be considered scientifically unsound."

The minimum loss by evaporation was observed in August at a depth of 75 cm. (about 29.55 in.) in a soil where oats were grown.

The penetration of the water was most rapid in the soil where vetch was grown. Where potatoes and rye were grown the moisture was noticeably con-
stant during the first period of vegetation. After harvesting, however, the potato soil lost the water with much greater rapidity.

The penetration of rainfall in the soil was found to be comparatively rapid, in some cases reaching a depth of 125 cm. (about 49.25 in.) within 7 days after rains occurred.

Soil moisture. J. CASCÓN (BoL Agr. Téc. y Econ., 3 (1911), No. 29, pp. 464—485, dttms. 3).—This article reports and briefly discusses the results of tests conducted at Patencia, Spain, bearing on the moisture of different soils in relation to fallowing, cultivation, and kind of crop grown. Observations on rainfall and evaporation from February to June, inclusive, during 1908, 1909, and 1910, are also reported.

The absorption of aqueous vapor from the air by soils, E. PACHECO (Asoc. Espan, Prog. Cien. Cong. Zaragoza, vol. 4, pt. 1, pp. 161—169; abs. in Geol. Zentbl., 15 (1910), No. 8, pp. 386, 387; Wasser u. Abnussr, 4 (1911), No. 1, p. 22).—Referring to the observation by geologists that more water is annually evaporated from the soil than falls in the form of rain, the author attempts to explain how this deficiency is made up and maintains that it is done by direct absorption of the aqueous vapor of the air by the soil. He cites a number of cases (Canary Islands and Estremadura) of maintenance of vegetation by water from this source in regions where almost no rain falls.

Biological-chemical processes in the soil, W. MOOSER (Landw. Vera. Stat., 75 (1911), No. 1—2, pp. 53—106; abs. in Jour. Chem. Soc. [London], 100 (1911), No. 554, II., p. 530).—The author reviews the work of other investigators bearing on the subject and reports the results of experiments on the influence of calcium carbonate, benzoic acid, and cresol on nitrification, loss of ammonia from increased application of lime, formation of nitrates in sterilized soils and in washed soils without addition of ammonia, and on the "dephenolizing" power of soils as determined by its action on para cresol as affected by temperature of the soil and period of application of the cresol.

Among the more important results obtained it is noted that the benzoic acid exerted a depressing influence on nitrification in the soil and that on the other hand the presence of alkalis, in not too large quantities, tended to neutralize this effect.

The application of cresol at first inhibited nitrification, but after a period of 30 days the formation of nitrates was the same for soils with and without application of cresol. It is believed that the bacterial activity does not cause the formation of nitrates, but that there is another oxidation process which in the case of the cresol soils attacked and changed into other forms the abundant and finely divided carbon compounds, after which the normal process of oxidation of ammonia is resumed. It appears that the changing of the cresol was considerably influenced by the temperature, no energetic reduction setting in under 35° C. The author suggests that an explanation of this "dephenolizing" power of soils be looked for in a study of enzymatic and catalytic agents.

Production of acids and alkalis in the soil, A. D. HALL and N. H. J. MILLER (7. Internat. Cong. Appl. Chem. [London], 1909, Sect. VII, pp. 17, 18; abs. in Jour. Chem. Soc. [London], 100 (1911), No. 583, II., pp. 429, 430).—This article is based upon experiments at Rothamsted, showing that a long-continued application of ammonium salts resulted in the accumulation of free mineral and humus acids in soils deficient in calcium carbonate, to such an extent that nitrification was interfered with and nitrogen was assimilated in the form of ammonia. On the other hand, continued application of sodium nitrate produced an alkaline reaction and puddling of the soil.
On the fixation of phosphoric acid by the organic matter of the soil, A. Petit (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 29, pp. 1347–1351; abs. in Rev. Sci. [Paris], 39 (1911), I. Vo. 21, pp. 667, 668; Chem. Zentralbl., 1911, II, No. 3, pp. 157, 158; Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Int., and Plant Diseases, 1911, No. 5, p. 1038).—The author concludes from his experiments that in soils very rich in organic matter, such as the forest soils with which he experimented, the fixation of phosphoric acid by humus was so small as to be negligible. The same was true of humus extracted from soils by ordinary methods.

Changes induced by the addition of carbohydrates to soils. H. B. Hutchinson and F. S. Mark (7. Internat. Cong. Appl. Chem. [London], 1909, Sect. VII, pp. 37–40; abs. in Jour. Chem. Soc. [London], 1909 (1911), No. 583, II, pp. 430, 431).—Experiments are referred to in which, when starch was applied at the rate of 1 ton per acre, the yield of barley was decreased 17.45 per cent, and an equal application of sucrose resulted in a decrease in the yield of 31.2 per cent. An examination of the soil showed a greatly increased growth of bacteria and molds. In culture tests it was found that 2 per cent of starch and dextrine increased the growth of bacteria and molds, but that mannitol did not produce this result.

Sewage sickness in soil, and its amelioration by partial sterilization. E. J. Russell and J. Golding (Jour. Soc. Chem. Indus., 39 (1911), No. 8, pp. 471–474).—Examinations of samples of soil which had become “sick” and more or less bacteriologically inactive as a result of continuous application of sewage showed that prolonged aeration under very favorable conditions did not restore the bacterial activity, but that partial sterilization by heat, carbon bisulphid, or toluol did bring about this result. The authors attribute the difficulty to the presence in the sewage-sick soils of large numbers of organisms which feed upon the bacteria to which sewage purification is due. The number of bacteria in partially sterilized soils rose to over 400,000,000 per gram, while in untreated soil they only occasionally reached 40,000,000. It was found that destructive organisms, including amœbe, Vorticella putrina, Euglena, and others, which are found in ordinary soils, were also present in the sewage-sick soils and were much more active there than in ordinary soils. These organisms were not killed by aerating, liming, or resting the soil, but were destroyed by heating and application of carbon bisulphid and toluol. Sewage-sick soils so treated were more effective as filters than untreated soils and did not so quickly lose their efficiency.

Carbon bisulphid as a soil improver, C. J. J. van Hall (Teysmannia, 22 (1911), No. 2–3, pp. 152–162).—This is a brief review of investigations bearing on this subject with references to the principal literature.

Conservation of the purity of the soil. H. L. Bolley (Proc. Soc. Prom. Agr. Sci., 31 (1910), pp. 100–106).—As in previous articles (E. S. R., 24, p. 132) the author maintains that there are large areas of wheat soils of the Northwest which have declined in productiveness as a result of contamination with disease-producing parasites and in this respect are analogous to old flax-cropped lands. “Constant cropping has carried to the soil the various types of parasites which the wheat crop and flax crop are heir to.”

The influence of the soil on plant growth, S. T. Parkinson (Jour. South-cast. Agr. Col. Wye, 1910, No. 19, pp. 258–261, pl. 1).—This is an account of comparatively simple tests to show the character of growth made by carrots on different types of soil, including peat, loam, clay, sand, and chalk. The experiments were made in pits filled with the soils.
The economical maintenance and development of soil fertility, C. E. Thorne (Bicen. Rpt. Tenn. Dept. Agr., 1909–10, pp. 284–500).—This article describes the system of rotation, the use of manure reinforced with ground rock phosphate, growth of clover, and application of lime and commercial fertilizers followed at the Ohio Experiment Station in increasing the productiveness of the soil.

The development of the use of manures and fertilizers, F. Schack (Verhandl. Naturw. Verein. Hamburg, 3. ser., 17 (1909), pp. LXX–LXXII).—The author concisely reviews the development of the use of manures and fertilizers from the earliest ages to the present time, and in conclusion points out that the object sought in the use of fertilizers, according to Liebig’s theory, should be to find the optimum amount of fertilizer to use with each soil and to avoid the use of anything more than this.

Stable manure and green manuring, Schneidewind (Ber. Landw. Reichsanst. Innern [Germany], 1910, No. 17, pp. 69–77).—This article, based upon experiments at Halle, deals with the composition, deterioration, and preservation of manure, and the effect of stable manure and of green manures on different crops.

The results indicate that the most profitable returns can be obtained in the case of root crops only by the use of manure with commercial fertilizers. About 25 per cent of the nitrogen of the manure was found to be utilized in the course of two years. It was thought that the beneficial effect of the manure was due to a considerable extent to the potash and phosphoric acid which it contained.

Green manures were found to give best results on light soils poor in humus and nitrogen. The crops which appeared to be best suited to culture with green manures were beets, potatoes, and oats. The sugar content of beets was slightly depressed by green manures, but to a less extent than by stable manure. The effect of the green manures on potatoes was very variable, but they were less beneficial than stable manure. The beneficial effect of the green manures was increased by thorough cultivation. Oats made a most decided response to green manures.

The Halle experiments indicate that green manures should not be plowed under deeper than 25 cm. (about 9.85 in.). On light soils they should be plowed under in late fall, winter, or early spring, while on better soils they give best results when plowed under before frost in the fall. In the case of light soils early plowing under is likely to result in loss of nitrogen. It was found profitable to use a small amount of nitrate of soda in addition to green manure on light soils, and on all soils a basal fertilizer containing potash and phosphoric acid is recommended.

The deterioration of manures under semiarid conditions, W. P. Headen and E. Douglass (Colorado Sta. Bul. 168, pp. 32).—This bulletin is based upon examinations of a large number of samples of sheep and cattle manure of various ages and kept under different conditions of moisture and exposure.

The main facts brought out in the bulletin are that manure under arid conditions does not lose weight as rapidly as in more humid regions. Sheep manure lost 32.5 per cent in weight in about 15 months and 56.7 per cent in a little over 2 years. Such manure normally contains about 13 per cent less moisture than in moist climates.

The phosphoric acid decreased 42 per cent in 15 months and 59 per cent in 2 years, the loss in phosphoric acid agreeing quite well with the loss in weight.

Manures in semiarid regions differ most decidedly from those of humid climates in percentage of potash. Probably as a result of the light rainfall,
manures do not lose potash in dry climates, no loss of this constituent being observed in these experiments during the first 15 months. That this was not due to insolubility of the potash in water was shown by experiments in which air-dried sheep manure lost 45.7 per cent of potash, 22.6 per cent of phosphoric acid, and 39 per cent of nitrogen when washed with water. In the series of samples examined the potash, calculated on the basis of dry matter in the manure, increased from an average of 4.4 per cent in fresh manure to 6.3 per cent in one-year-old samples, remaining at this figure for several years. The phosphoric acid remained at about 1 per cent of the dry matter irrespective of the age of the manure.

There was a large loss of nitrogen during the first 2 years, mainly as a result of escape of free ammonia. Nitrogen as nitrates varied widely. Some of the older manures carried large amounts of nitrates while others of the same age contained almost none. The percentages of carbon and hydrogen in the manures were practically constant and were apparently not affected by age.

With the exception of insoluble ash, which increased with age, and free ammonia and nitrogen, which decreased with age, there was remarkable uniformity in composition, indicating that under the conditions of these experiments the manure was broken down by bacterial life at about the same rate that leaching carried away the soluble salts.

Recent investigations on the loss of nitrogen from manure. Vogel (Illus. Landw. Ztg., 31 (1911), No. 50, pp. 389, 390).—The results of several recent investigations on this subject are briefly summarized.

The theoretical basis for the use of commercial fertilizers, F. K. Cameron (Jour. Indus. and Engin. Chem., 3 (1911), No. 3, pp. 188-191).—"In this paper it is pointed out that: (1) Crop production is the result of many factors, natural and artificial, and these factors are all mutually dependent. (2) No simple theory of fertilizer action can satisfactorily account for the known facts. (3) With intensive methods of cultivation, fertilizers are effective on all kinds of soils, and are the more efficient on the naturally better soils. (4) Other materials than those containing the traditional plant foods may yet become valuable fertilizers, if they satisfy commercial requirements."

Applied electrochemistry, M. deK. Thompson (New York, 1911, pp. XII+329, figs. 137).—The portion of this book of special agricultural interest is the chapter on fixation of atmospheric nitrogen, which describes the preparation of calcium cyanamid, the oxidation of the nitrogen of the air, and the synthesis of ammonia, the three general methods of fixing atmospheric nitrogen now in operation.

Recent progress in the fixation of atmospheric nitrogen, J. B. C. Kershaw (Elect. World, 57 (1911), No. 17, pp. 1035-1038, figs. 5).—It is stated that there was considerable progress during 1910 in the industrial development of furnaces and processes for the fixation of atmospheric nitrogen. "It is estimated that 100,000 horsepower is already applied to these processes of manufacture, and that by the end of 1911 this total will be more than doubled." Several of the newer manufacturing plants are described and the efficiency of the different processes is discussed.

The industrial fixation of atmospheric nitrogen, E. Lamy (Soc. Ingén. Civ. France Bull., 1910, No. 7, pp. 61-86, figs. 6; abs. in Metallurg. and Chem. Engin., 9 (1911), No. 2, pp. 99-104, figs. 2; Ztschr. Elektrochem., 17 (1911), No. 11, p. 434).—The principal processes employed in the fixation of atmospheric nitrogen are discussed, particularly the Pauling process as in operation at Notre-Dame de Briançon, France.

Hydro-electric plants in Norway and their application, A. Scott-Hansen (Abs. in Mark Lane Express, 105 (1911), No. 4154, p. 635; Chem. Trade Jour,
An abstract is given of a paper read before the Faraday Society, dealing especially with the manufacture of nitrogen compounds from the air and showing the growth of this industry in Norway and elsewhere. It is stated that during the past year from 170,000 to 180,000 horsepower was used in the manufacture of nitrates (including nitrates of calcium, sodium, and ammonium) and 20,000 horsepower in the manufacture of calcium cyanamide.

Tests of nitrite in pot and field experiments, B. Schultz (Fühling's Landw. Ztg., 60 (1911), No. 10, pp. 336-351).—In comparative tests of calcium nitrite, calcium nitrate, and sodium nitrate it was found that the yield of cereals was reduced to a marked extent in the case of calcium nitrite. The author concludes, therefore, that nitrite is an objectionable constituent of commercial calcium nitrate for fertilization purposes.

The fertilizing value of so-called nitrammon-lime, II, H. G. Söderbaum (K. Landth. Akad. Handl. och Tidskr., 50 (1911), No. 4, pp. 335-351, figs. 6).—In continuation of previous experiments (E. S. R., 22, p. 432), the author studied particularly the after effects of this material during a second season. The effect of both phosphoric acid and nitrogen in the material was relatively small, its fertilizing value depending primarily upon its lime content.

Nitrogen and phosphorus as related to permanent agriculture, C. H. Lane (Blen. Rpt. Tenn. Dept. Agr., 1909-10, pp. 301-307).—This article discusses the need for nitrogen and phosphorus in middle Tennessee soils as indicated by cooperative fertilizer experiments.

Texas phosphates, W. D. Hornaday (Amer. Fertl., 3, (1911), No. 8, p. 36).—This is a brief note referring to reported discoveries of a large deposit near Austin, Texas.

Possible sources of potash, H. Erdmann (Abs. in Engin. and Min. Jour., 91 (1911), No. 21, p. 10/4).—The author dismisses the salt deposits of France, Austria, the Caspian region in Russia, and those of Tibet as unimportant on account of the small percentage of potash present, but attributes greater importance to the salt deposits of northwestern Mexico, Arizona, and the Salton Sea region of southern California, which he estimates to contain at least 200,000,000 tons of potassium chlorid. A certain amount of potash may also be obtained as a by-product of the sodium nitrate industry of Chile. On the whole, however, the author thinks "no considerable foreign competition threatens the German potash industry in the near future."

Potash fertilizers, F. Brunerie (Jour. Agr. Prat., n. ser., 21 (1911), No. 5, pp. 111-133).—Summarizing the results of 5 years' field experiments, the author concludes that the use of potash salts was profitable on a soil containing 0.01 per cent of potash and 0.008 per cent each of nitrogen and phosphoric acid and with a variety of crops.

A new method of using potash salts and other fertilizers, L. Hiltner (Mitt. Deut. Landw. Gesell., 26 (1911), No. 19, pp. 231-233).—This article gives the results of comparative tests of kainit, calcium nitrate, magnesium sulphate, ferrous sulphate, milk-of-lime, humus, and various other substances applied to the above-ground portion of potatoes and other crops, which indicated a marked fertilizing effect from several of these substances applied in this way. In other experiments potassium chlorid, sulphate, and phosphate
SOILS—FERTILIZERS.

were applied to the soil and painted upon the leaves of the plant. In the majority of cases better results were obtained by the latter method of application than by the former. The author urges further investigations along this line.

The rational use of lime, W. P. Brooks (Massachusetts Sta. Bul. 137, pp. 3-6).—This article discusses briefly the possible effects of liming, how to determine what soils need liming, the relation of lime to crops, and methods of supplying lime.

The distribution, composition, and cost of lime, H. D. Haskins and J. F. Merrill (Massachusetts Sta. Bul. 137, pp. 7-19).—This article gives information regarding the sources of lime in Massachusetts, the composition of different forms of lime, and analyses and valuations of samples of commercial lime. The kinds of lime suited to different conditions are indicated.

Lime: Its properties and uses (U. S. Dept. Com. and Labor, Bur. Standards Circ. 30, pp. 22).—This circular deals with methods of manufacture, properties, and use of lime as a building material, in chemical industries, and in agriculture. Methods of testing lime are briefly referred to. The essential facts regarding the use of lime as a fertilizer are concisely summarized from publications of this Department and the state experiment stations.

Action of sulphur as a fertilizer, E. CHANCIN and A. DESRIOT (Journ. Agr. Prat., n. ser., 21 (1911), No. 14, pp. 427-429; abs. in Engrais, 26 (1911), No. 25, pp. 684, 685. Rev. Gén. Sci., 22 (1911), No. 10, pp. 392, 393).—The authors refer to experiments made in Germany in 1909 in which it was found that the use of sulphur for potato diseases was not only effective in reducing the disease but increased the yield of potatoes, and report experiments of their own in which sulphur was used at rates of from 250 to 500 kg. per hectare (about 223.14 to 446.28 lbs. per acre) in connection with superphosphate, potassium sulphate, and sodium nitrate on potatoes and beets. In all cases there was a decided increase in the yield of potatoes on the plats receiving sulphur, and in every case except one there was an increase in yield of beets following its application.

While the authors do not attempt general conclusions from these experiments, they suggest that the beneficial effect of the sulphur may be due to action similar to that of partial sterilization by heat, carbon bisulphid, toluene, etc.

Sulphur requirements of farm crops in relation to the soil and air supply, E. B. HART and W. H. PETERSON (Wisconsin Sta. Research Bul. 14, pp. 21).—This bulletin describes an improved method of determining sulphur in soils (fusion with sodium peroxid) and gives compiled and original data on the amounts of sulphur in feeding stuffs, in soils under different conditions, removed from soils by crops and lost in drainage, and added to soils by precipitation and in manure.

It is shown that "normal soils are relatively poor in total sulphur trioxid; a limited number of analyses showed a percentage content of from 0.033 to 0.140; most of them contained less than 0.10 per cent. An acre-foot will contain from 1,000 to 3,000 lbs. of total sulphur trioxid. About the same quantity of phosphorus pentoxid will be found in an acre-foot of normal soil. These results for sulphur trioxid are based on analyses made by the method of fusion with sodium peroxid. Determinations by extracting with hydrochloric acid or with nitric acid and bromin will not give the total sulphur content of soils. Soils cropped from 50 to 60 years and either unmanured or receiving but slight applications during that period have lost on the average 40 per cent of the sulphur trioxid originally present as determined by comparison with virgin soils.

a Deut. Landw. Presse, 37 (1910), No. 18. p. 204."
"The sulphur content of a number of . . . common farm products . . . is much larger than found by Wolff in the ash from such products.

"The amount of sulphur trioxid removed by crops is considerable, being equal in the case of average crops of cereal grains and straw to about two-thirds of the phosphorus pentoxid removed by these crops; the grasses of mixed meadow hay remove quite as much sulphur as phosphorus, while the legume hays may approach, and in the case of alfalfa, even exceed in this respect. Members of the Crucifere, as the cabbage and turnip, are heavy sulphur-using crops and may remove two to three times as much sulphur trioxid as phosphorus pentoxid. An average acre crop of cabbage will remove about 100 lbs. of sulphur trioxid."

It is estimated that the gain from precipitation in the region of Madison does not amount to more than 15 to 20 lbs. per acre annually, while the loss in drainage amounts to about 50 lbs. per acre yearly.

"The fact that common crops remove from the soil considerable quantities of the element sulphur, while the compensating factor of supply from the atmosphere is very probably offset by the losses which the land sustains by drainage, makes it apparent that for the maintenance of a permanent supply of sulphur in the soil, this element must be added systematically either as a constituent of commercial fertilizers, or with the farm manure."

The method used in the determination of sulphur in soils was as follows:

"Ten gm. of soil were placed in a 100 cc. nickel crucible, moistened with water, about 10 gm. of a weighed 20 gm. portion of sodium peroxid added, and the mixture thoroughly stirred with a platinum rod. The crucible was placed over an alcohol flame and heated moderately until the mass was dry. The remainder of the sodium peroxid was then added, the cover placed on the crucible, strong heat applied until the mass melted, and kept in this condition for 10 minutes. It was then allowed to stand over a lower flame for 1 hour. The crucible was removed, cooled, placed in a 600 cc. casserole, hot water added and the fused mass removed. It was neutralized with hydrochloric acid and then further acidified with 10 cc. of hydrochloric acid. The volume was made up to about 450 cc. and boiled for 15 minutes, or until no undecomposed portion of the fused mass remained on the bottom. The covered casserole was allowed to stand on the steam bath over night, filtered through a 'nutsche' and the residue thoroughly washed with successive small portions of hot water. The filtrate and washings, if over 500 cc., were evaporated below that volume, re-filtered, and the volume made up to 500 cc. Aliquots of 250 cc. each were heated to boiling, barium chlorid added, boiled for 5 minutes, and set aside on a steam bath for 24 hours. The volume was not allowed to decrease as silicic acid may be precipitated if much evaporation takes place. After standing for this length of time the barium sulphate was filtered off, washed, ignited and weighed. In the determinations made by this method the precipitate was free from silica as demonstrated by the hydrofluoric acid test."

This method gave considerably higher results than the official method and somewhat higher than the nitric-acid-bromin method (modified) of Van Bemmelen.

The sulphur requirements of farm crops in relation to the soil and air supply, E. B. Hart and W. H. Peterson (Jour. Amer. Chem. Soc., 33 (1911), No. 4, pp. 539-561; abs. in Journ. Chem. Soc. [London], 100 (1911), No. 583, II, p. 431).—This is an account of the investigations noted above.

Catalytic fertilizers in the culture of beets, G. Bertrand (Rev. Sci. [Paris], 79 (1911), I, No. 22, pp. 673-680).—The author shows the general distribution of manganese in plants and maintains that this substance is essential to the oxidizing action of oxydases, laccases, etc., which in turn is essential to the
vital processes of the plant, and he reports experiments showing that manganese has a marked effect upon the growth of Aspergillus niger, oats, and beets. Similar effects have been observed in the case of aluminum, boron, iron, zinc, and the like, and this is attributed by him to catalytic action.

The use of kelp and rockweed as a fertilizer (Maritime Farmer, 16 (1911), No. 17, pp. 623, 624).—This article discusses briefly the source of supply and the best methods of using kelp and rockweed as a fertilizer in Newfoundland. The material is considered a valuable fertilizer resource for the region.

Value of tobacco juice residues as manure (Bot. Tec. Colitiv. Tabacchi [Scalfati], 9 (1910), No. 6, p. 339; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 1911, No. 1, p. 65).—Analyses are reported showing that the pressed tobacco extract examined in this case contained dry matter 67.5 per cent, phosphoric acid 0.24 per cent, potash 0.22 per cent, and nitrogen 0.96 per cent.

Purchasing a fertilizer, R. C. Thompson (Arkansas Sta. Circ. 11, pp. 4).—This circular attempts to explain briefly “a means of telling which fertilizers are the cheapest to buy,” and as illustrating the importance of the matter the author states that “in some instances farmers pay as high as 36 cts. a pound for nitrogen in a low grade fertilizer when they could just as well buy a higher grade fertilizer in which the nitrogen costs only 26 cts. per pound.”

Commercial fertilizers, E. Fulmer (Washington Sta. Popular Bul. 37, pp. 4).—This gives a brief summary of facts relating to the use and inspection of fertilizers, more fully presented in Bulletin 98 of the station (E. S. R., 25, p. 219).

Commercial fertilizers, W. J. Jones, Jr., et al. (Indiana Sta. Bul. 151, pp. 59–163, fig. 1, map 1).—This bulletin gives the results of analyses of fertilizers inspected in Indiana during 1910, comparing the general results with those obtained in previous years. The text of the state fertilizer law is also given, with notes on the requirements of the law as related to manufacturers, agents, dealers, and consumers. It is estimated that 151,865 tons of fertilizer, valued at $3,695,492, was sold in Indiana in 1910.

Analyses of commercial fertilizers, M. B. Hardin et al. (South Carolina Sta. Bul. 154, pp. 56).—This bulletin contains the results of analyses and valuations of 1,188 samples of fertilizers examined during the season of 1909–10.

Terms used in the chemical fertilizer trade and superphosphate industry (Saaten, Dünger u. Futtermarkt, 1911, No. 25, pp. 693–696).—The terms agreed upon for the designation of fertilizer compounds and mixtures by the German Agricultural Council and the Association of German Fertilizer Manufacturers are given.

AGRICULTURAL BOTANY.

Translocation of plant food and elaboration of organic plant material in wheat seedlings, J. A. Le Clerc and J. F. Breazeale (U. S. Dept. Agr., Bur. Chem. Bul. 138, pp. 32, figs. 2).—The results of a study of wheat seedlings grown for 2 weeks in water cultures, to different series of which sodium nitrate, potassium sulphate, potassium chlorid, and sodium phosphate were added, are given, showing the changes taking place in inorganic and organic constituents.

The authors found that the nitrates are taken up somewhat more readily than phosphates, but not nearly to the extent that potash is absorbed. There is apparently a selective absorption on the part of the plants, large amounts of potash being assimilated. This is brought about by the immediate requirements of the plants for a large amount of potash for the proper exercise of their physiological functions.
In the changes of organic constituents analyses were made for ether extract, fiber, pentosans, and sugars before and after inversion. The largest amount of ether extract was elaborated by the seedlings grown in nitrate and in phosphate solutions. The percentage of fiber in the axes of the plant was approximately the same, irrespective of the kind of solution in which the plants were grown. In the case of the pentosans, at the end of the fifteenth day there was a somewhat larger amount in the axes of plants grown in nutrient solutions than in the control, but in the results obtained it does not appear that nitrates form any larger amount of pentosans than is formed by potash or phosphoric acid.

During the process of growth the formation of reducing sugar in the seed was found to increase rapidly up to the fifth or sixth day; after this time there was a rapid falling off in the reducing sugars until at the end of 15 days there was but a trace of this substance in the residual seed. In the axes, however, reducing sugars increased up to about the ninth day, when they contained about 3 times as much of the sugars as the original seed did of hydrolyzable sugar. After this period there was a gradual decrease of reducing sugars, even in the axes, until the fifteenth day, when the amount present approximated that of the hydrolyzable sugar originally present in the seed. The total amount of hydrolyzable sugar never exceeded that originally found in the seed, indicating that either the hydrolyzable sugar is translocated as such from the seed or that it is hydrolyzed before translocation occurs. No reducing sugar was present at the beginning, but on the fifth day it had increased to twice the total hydrolyzable sugar originally present. Whether the sugars found in the axes are due entirely to the hydrolysis of the starch of the seed and subsequent translocation into the axes, or whether a part of these sugars was a result of assimilation, was not determined.

On the biochemical side of carbon dioxide assimilation by green plants, V. GRAFE (Biochcm. Ztschr., 32 (1911), No. 2, pp. 114–128).—This is a general discussion of the photosynthetic process, especially with reference to the presence, origin, and use of formaldehyde in green plants. It contains a review of various investigations and experiments on this subject and on the effect of formaldehyde on green plants (E. S. R., 25, p. 434).

On the rôle of nucleoprotein in plants, W. ZALESKI (Ber. Deutsch. Bot. Gesell., 29 (1911), No. 3, pp. 146–155).—In a study of this subject the author determined the amount of nucleoprotein in the leaves of Tilia taken in different stages of growth, in the etiolated seedlings of *Zea mays* in different stages of germination, in the seeds of *Vicia faba* germinated in darkness, in the etiolated seedlings of wheat in various stages of growth, and in other plants.

From these investigations the conclusion is reached that nucleoprotein consists of formative material which takes part in the building up of the proplasts of the plants.

The physiological importance of manganese and of aluminum in the vegetable cell, J. STOKLASA (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 20, pp. 1340–1342).—The author gives the results of experiments on plants grown in liquid cultures and in pots of certain amounts of salts of manganese and aluminum. When 1/2,000 of the atomic weight in grams of manganese and of aluminum was added to culture media the plants made the highest yields, and of all the organs of the plants the leaves showed the largest quantities of both salts. It is, therefore, believed that these 2 elements not only take part in assimilation processes, but may also play an important rôle in the photosynthetic process.
On the movements of the metabolic products of the leaf through uninjured, chloroformed, and plasmolyzed petioles, N. T. Deleano (Jahrb. Wiss. Bot. [Pringsheim], 39 (1911), No. 2, pp. 129-186, figs. 9).—A study is reported of the time necessary for the complete disappearance from the leaf tissues of the primary starch formed by photosynthesis, and of the route of the unused foodstuffs in their journey through the leaf stem or petiole, as indicated by experiments with uninjured, chloroformed, scalded, and plasmolyzed petioles.

It was found that in uninjured leaves the starch entirely disappeared in from 33 to 46 hours, and that not only carbohydrates but other metabolic products passed out of the leaves, the carbohydrates being 1.06 per cent of the fresh substance and the noncarbohydrates 1.63 per cent. The experiments indicated that the bulk of the metabolic products usually passed through the central fibrovascular system of the petioles.

Light and the behavior of organisms, S. O. Mast (New York and London, 1911, pp. XI+310, figs. 55).—This is an extensive study of the processes of orientation in plants and animals, especially those without eyes—that is, as to how these organisms regulate their activities so as to bend or move toward or from the source of stimulation.

The text is divided into 4 parts, viz, an introduction and historical review concerning the origin and development of disease and theories regarding movements in plants and animals, with special reference to the question of tropisms; experimental data and discussions bearing on the question as to how organisms bend or turn and move toward or from a source of stimulation; and general considerations of reactions to light and reactions in light of different wave lengths or colors.

Organic and functional changes of plant organs under the influence of radium, G. Fabre (Compt. Rend. Soc. Biol. [Paris], 69 (1910), No. 36, pp. 523, 524).—The author reports the results of experiments with the unopened flower buds and ovaries of Lilium when exposed to radium rays of different strengths.

It was found that the buds when subjected to strong radium rays were arrested in their development and soon commenced to dry up, while the ovaries and stigmas were completely atrophied and the anthers either did not develop completely or were greatly retarded in maturing.

A histological study of the anthers and ovaries showed that the pollen grains had either no nuclei in them, or the nuclei only incompletely developed. Sections of the stigma showed a sufficient number of pollen grains present for proper fertilization, but that no growth of the pollen grains had occurred. In the ovaries not only were the embryo sacs atrophied, but the entire ovule also.

The action of radium on plant structures, G. Fabre (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 11, pp. 319, 320).—In a further study of this subject (see above) the author discusses the organic and functional changes that occur in plant structures after exposure to radium rays, and the influence on the germination of Linum catharticum of different amounts of radium bromid when present in a given amount of soil.

It was found that when Lilium rhizomes, the flowers of which had been previously subjected to radium rays, were replanted they either rotted or failed to grow, from which the author concludes that the exposure of the reproductive organs to strong radium rays will cause a general derangement of the vegetative organs.

In the experiments with L. catharticum a general retardation was observed in the germination and development of this plant from the presence of the radium salts in the soil. There was also an appreciable increase in the number of leaves developed on the plants subjected to the radium rays when compared with normally grown plants.

9204°—No. 6—11——3
The relation of parasitic fungi to the contents of the cells of the host plants.—I. The toxicity of tannin, M. T. Cook and J. J. Taubenhaus (Delaware Sta. Bul. 91, pp. 3-77, pls. 10).—The authors give the results of experiments with certain fungi in which the influence of tannin on their germination and growth was tested. The fungi were grown in various media to which various percentages of tannin had been added. Three species of Colletotrichum, 8 species of Gloeosporium, Glomerella rufomaculans, 12 species of Fusarium, several species of Ceratostomella, Corticium alutaceum, Leotium squamulosum, 2 species of Graphium, 4 species of Cladosporium, Alternaria solani, Spathulopsis udum, Sclerotinia fructigena, Diaporthe parasitica, Penicilium candida, 3 species of Penicillium, Nocosmospora vasinafesta, Guignardia bidwillii, Septoria verbasci, Ascochyta pisii, Cephalothecium roscum, some undetermined species of Phyllosticta, Rhizoctonia, and Phoma, Cladosporium macrocarpum, Aspergillus, 3 rusts, and 1 smut were grown on certain media and the results noted.

It was found that the first action of tannin is to inhibit or check germination and finally to kill the spores. Low percentages of tannin in distilled water may stimulate germination and growth and seem apparently to serve to some extent as a food. As the maximum percentage of tannin in which spores will germinate and grow is approached, the mycelium tends to become short, thick, and very septate. Tannin has a tendency to retard or inhibit the growth of fungi. The parasitic forms are more sensitive to the action of tannin than the saprophytic ones. The majority of the parasitic fungi tested were retarded by from 0.1 to 0.6 per cent tannin. The fruiting was frequently stimulated by low percentages of tannin. The action of tannin is practically the same whether the organism is grown in agar or in liquid media.

The origin of the chloroplasts in the cotyledons of Helianthus annuus, E. C. Miller (Bot. Gaz., 51 (1911), No. 5, pp. 378-384, pl. 1).—After a review of the opinions of various investigators on this subject, the author gives the results of a study of H. annuus seedlings when grown under greenhouse conditions at a temperature of from 65 to 75° F.

From a study of the sections of the seedlings at various stages of growth the conclusion is reached that chloroplasts are present in the resting seed, but are very minute, and that as the seeds germinate these chloroplasts increase in size and multiply by simple fission, thereby giving rise to chloroplasts of the mature seedlings.

Dimorphism of the gametes of CEnothera, H. de Vries (Biol. Centbl., 31 (1911), No. 4, pp. 97-104; rev. in Science, 4. ser., 33 (1911), No. 858, pp. 897-899).—In a series of cross-fertilization experiments with certain species of CEnothera the author found that the ovules and pollen grains carry different hereditary tendencies, for in reciprocal crosses with O. biennis and O. muricata the resulting hybrids were very unlike and strongly patroclinic, showing in both instances only slight traces of any influence by the female parent. The common O. biennis represents the form inherited from the pollen, while the ovule characters are recessive.

This property of producing gametes having diverse hereditary qualities is termed “heterogamie” by the author. When the reciprocal hybrids of the same 2 parents are crossed, the resulting hybrids are called double reciprocal hybrids, in which, if a patroclinic hybrid is crossed with the pollen of the paternal species, what the author calls iterative hybrids results, exactly like the first hybrid and very like the paternal species. If, on the other hand, a patroclinic hybrid is crossed with pollen of the mother species, the resulting hybrids will have the grand-paternal species eliminated, and are called sesqui-reciprocal hybrids.
In the review of this article by W. T. Swingle the name "heterogamie" applied to this dimorphism of the gametes by de Vries is rejected as being one used in too many different senses, and the term "allogametism" is proposed in its place. Then the pollen grains and ovules of O. biennis and O. muricata would be called "allogametes."

Hereditary characters and their modes of transmission, C. E. Walker (London, 1910, pp. XII+239, figs. 21).—The present volume is an attempt to apply recent discoveries as well as experimental work upon cells to some problems in heredity, thereby harmonizing the results of the Mendelian experiments with the observations of the biometricians. This the author claims to have done by showing that some parts of the cell involved in fertilization are distributed in an alternative manner, while other parts simply divide in bulk. Two classes of characters which behave in different manners in regard to inheritance are suggested, one individual and the other racial, each with a different mode of transmission.

Suggestions concerning the terminology of soil bacteria, J. G. Lipman (Bot. Gaz., 51 (1911), No. 6, pp. 454-460).—After calling attention to the general confusion existing in the terminology of the soil bacteria, the author suggests arranging the groups of these organisms according to their physiological functions.

The following grouping is suggested and its merits are discussed: Ammono- and de-ammono-bacteria, nitro- and de-nitro-bacteria, proteo- and de-proteo-bacteria, azoto- and de-azoto-bacteria, sulpho- and de-sulpho-bacteria, and ferri-bacteria; the corresponding terms are ammonification and deammonification, nitrification and denitrification, proteofication and deproteofication, azotofication and deazotofication, sulphofication and desulphofication, and ferrification and deferrification.

The influence of bacteria upon soil fertility, C. M. Hutchinson (Agr. Jour. India, 6 (1911), No. 2, pp. 97-113, pls. 4).—After a general discussion of the effects of tillage, irrigation, drainage, and manuring on the activity of certain soil bacteria, the author describes the methods in use in his laboratory to determine the reaction of soils to various agricultural operations involved in soil bacteriology. These include methods used in plating soil bacteria and in studying nitrification and ammonification in soils.

Bacteriological methods for the estimation of soil acidity, J. G. Lipman (Science, n. ser., 33 (1911), No. 860, pp. 971-973).—It is claimed that no satisfactory method has yet been found for measuring accurately the acidity of soils. The author suggests using the well-known fact that bacteria as a rule do not flourish in acid media, by inoculating neutral bouillon media with varying amounts of the acid soil under investigation and noting the resulting bacterial growth.

Preliminary experiments along these lines have demonstrated that the amount of acid present in cultivated soils may be determined quite accurately by comparing bouillon of varying reactions with equivalent quantities of neutral bouillon containing varying amounts of soil, or different quantities of soil may be added to measured amounts of bouillon, then sterilized and inoculated with a standard culture of ammonifying bacteria, and the varying amounts of ammonia given off used as a measure of the soil acidity.

The bacteriotoxins and the "agricere" of soils, Greig-Smith (Centbl. Bakt. [etc.], 2. Abt., 30 (1911), No. 7-12, pp. 154-156).—The author gives a brief preliminary note on work done in the laboratory of the Linnean Society of New South Wales, in which the presence of bacteriotoxins in soils is investigated.

The author claims that such toxins are undoubtedly present in the soil, and that he has extracted a greater quantity from a poor soil than from a good one.
The experiments were made with *Bacillus prodigiosus* and with mixed bacteria of the same soil from which the extract tested was obtained. The toxic action was greater with *B. prodigiosus* than with the mixed soil bacteria. In other words, the latter exhibited a certain degree of immunity toward their own toxins.

It is claimed that the toxin contained in the soil is soluble in dilute saline solutions, is partially destroyed at 94° C., rapidly decays in aqueous solution, is converted by boiling into a nutrient, is destroyed by sunlight, and will decay during storage of the soil in an air-dry condition. The power of the toxins is not diminished by sodium chloride, potassium sulphate, or magnesium sulphate solutions, as the toxic effects of extracts of soil made with a 0.5 per cent solution of these compounds were very pronounced.

It is also stated that soil particles have a protective covering of soil wax, or agricere, which consists of sapoinifiable and unsapoinifiable residual organic matter of the soil. When disinfectants are applied to the soil, such as carbon bisulphid, chloroform, etc., their action is a double one. They kill off the less resistant bacteria, and dissolve agricere and carry it to the surface of the soil, thereby removing the waterproofing from the soil particles, and thus enabling the surviving bacteria to obtain a greater food supply. Heat, it is claimed, destroys the toxins and the less resistant bacteria, thus permitting the more resistant species to multiply very rapidly, due to the absence of the soil bacteria toxins.

Experiments on ammonia and nitrate formation in soils, II, J. G. Lipman, P. E. Brown, and I. L. Owen (Centbl. Bakt. [etc.], 2. Abt., 30 (1911), No. 7-12, pp. 156-181).—In an earlier communication (E. S. R., 23, p. 621) the authors showed that ammonia formation may serve as an index of the intensity of decomposition processes in the soil. In this paper further tests of the accuracy of this method and additional data on the decomposition of protein compounds in the soil are reported, including detailed studies on ammonia formation from dried blood as affected by the mechanical composition of the soil, ammonia production as affected by moisture relations, the relations of lime to ammonification in soils, and the influence of chemical and physical factors on ammonia formation.

Taken as a whole, the experiments reported furnished convincing evidence, so the authors claim, as to the accuracy of the method employed, that is, of using the formation of ammonia as a criterion of the intensity of the decomposition processes in the soil.

On the rôle of nitrate reduction in the metabolism of denitrifying bacteria, O. Wegner (Welche Rolle spielt die Nitratreduktion im Stoffwechsel der denitrifizierenden Bakterien? Inaug. Diss., Univ. Berlin, 1910, pp. 32; abs. in Bot. Centbl., 116 (1911), No. 10, pp. 267, 268).—The experiments here reported were carried on with *Bacterium actinopelle* in culture media containing peptone, hemoglobin, and albumin as a source of nitrogen, but containing no amid substances.

The addition of galactose, levulose, and dextrose to the culture media stimulated the growth of the fungi and the reduction of the nitrates and nitrites to nitrogen. The amount of calcium nitrite in the culture media did not exceed 1 per cent, but the most intense nitrite decomposition occurred in a 0.25 per cent solution.

In the decomposition of nitrates by the bacteria 2 stages occurred, viz. first, the change from nitrate to nitrite, and second, the reduction of the nitrites to free nitrogen and nitrous oxid. It was found that anaerobic conditions in the culture media greatly increased the nitrite reduction.
Legume bacteria, S. F. Edwards (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 36 (1910). pp. 162, 163).—The author reports the work done on the preparation of various cultures of nitrogen-fixing organisms for inoculating the seeds of alfalfa and other legumes, and the results of their use by various farmers. Many farmers report a greater vigor and increased yield ranging from 10 to 50 per cent from the use of the inoculated seeds.

Three general groups of nitrogen gatherers are mentioned, viz, the anaerobic species, with Clostridium as a type, the aerobic represented by Azotobacter species, and the symbiotic root nodule bacteria. In addition to the nitrogen-gathering root tubercles of the Leguminosae, the author lists as probable nitrogen gatherers the organisms found in the root tubercles of alder (Alnus crispa), Ceanothus americanus, Leparygryca canadensis, Eleagnus arvecula, Ceanothus velutinus, Comptonia peregrina, Euphalartos villosus, E. horridus, Cycas scehanni, and C. circinitalis.

It is claimed that the economic maintenance of the agricultural nitrogen supply depends upon determining the proper roles of these various activities, the possibilities of the control and economic enhancement of their desirable functions, and the recognition of the practical limits of biological factors in farm practice, as well as on when and how to use nitrogen fertilizers profitably.

Studies on the organisms found in the root tubercles of cycads, F. ZACH (Österr. Bot. Ztschr., 60 (1910), No. 2, pp. 49-55).—In addition to bacteria and an alga (Anabora cycadearum) the author found in the root tubercles of Cycas revoluta an intracellular hyphomycete the mycelium of which becomes digested in a manner similar to that of the mycelium of the fungus in the root tubercles of Eleagnus and Sempervivum (E. S. R., 23, pp. 528, 629).

The nucleus of the infected cell becomes degenerate and the starch disappears, while there is an increased production of calcium oxalate in connection with a diminished resistance of the cell invaded by the parasite.

FIELD CROPS.

A statement as to the weeds which have proved most troublesome during the season 1909-10 is followed by a discussion of the remedy for field bindweed (Convolvulus arvensis). Among 10 weeds mentioned as recent introductions full notes are given on Rocket (Eruca sativa), pineapple weed (Matricaria suaveolens), and yellow or small eyssium (Alyssum alyssoides).

From several years’ tests of the efficiency of iron and copper sulphate in the destruction of mustard in grain crops it is stated that both substances are successful, but that iron sulphate is the more satisfactory. On one farm a solution of 80 lbs. of iron sulphate to 40 gal. of water was applied by means of a potato sprayer with special broadcast attachment consisting of a rod about 11 ft. long with nozzles 16 in. apart. Although the mustard was very thick and the nozzles too low to allow the spray to spread sufficiently, every mustard plant was killed without injury to the oat crop.

Tables state the amount of rainfall during the 6 growing months of each of the past 11 years, the average grain yield during the past 28 years, and the
average grain and straw yields during the past 12 years of field peas and each of a number of grains.

In a test of 35 varieties of oats, potatoes, and the various types of barley and wheat grown continuously on the same farm only one variety showed as high a yield during the first year of the test as during the last, while only 6 showed as high a yield during either of the first 2 years of the test as during the last. The soil changed little in fertility and no plant selection was exercised, but on the whole the average yield per acre during the latter part of the period was greater than during a corresponding period at the beginning of the experiment.

Winter wheat, barley, and corn grown on both clover and timothy sod showed average yield of 44.7 per cent greater in case of the grain grown on clover sod. Oats, barley, spring wheat, and peas were grown for 5 years separately and in 11 different combinations of 2, 3, or 4 grains each. The average results show greater yields from the mixtures in from 90 to 95 per cent of the different tests. The highest yield of threshed grain per acre was obtained from a mixture of oats and barley, which excelled the yield of either grain grown separately by 200 lbs. Five years' tests indicate that greater yields were secured after the sowing of 1 bu. of oats and 1½ bu. of barley than when the mixture was supplemented by ½ bu. of flax, emmer, spring wheat, or hulless barley, the yield being actually decreased by the additional mixture of any one of these 4. In a 4-years' test barley and oats sown together produced the greater yield when seeded at the rate of 4 pk. of each per acre than when either was mixed in at a higher or lower rate, and produced a crop composed of 38 per cent of oats and 62 per cent of barley. The yields obtained from this mixture also excelled those obtained by sowing barley with emmer, rye, wheat, peas, or flax. Tables state some results obtained by sowing mixtures of 6 and 8 different grains made up in 2 ways, (1) by mixing equal weights of seed of all the varieties sown, and (2) by sowing the same amount of each variety that would be sown if it was being seeded separately. A very great influence on the yield was exercised by the barley, oats, and rye, a moderate effect by emmer, and a slighter effect by spring wheat, field peas, grass seed, vetches, and flax. No marked advantage was obtained by growing together different varieties of the same class of grains, as the yield obtained from the mixture closely approximated the average of the same varieties when sown separately.

In tests of various formalin, potassium sulphid, bluestone, and hot-water treatments for oat and wheat sown the greatest yields of both grains were secured from seed which had been immersed in a formalin solution for 20 minutes. Among the bluestone treatments the best results were obtained by immersing the seed for 12 hours in a solution of 1 lb. of bluestone to 25 gal. of water.

The sowing of smut-infected seed of different ages indicated that the smut spores retained their vitality longer than the grain and that the grain weakened by age was more readily attacked by the smut.

A report progress of selection and hybridization work with oats indicates good results with some varieties and crosses, and the hope that certain new varieties will soon be so constant as to justify confidence in their superior resistance to the varieties now generally grown throughout the Province of Ontario.

In a test of the stooling properties of 12 varieties of oats, the average number of stools per plant during 2 seasons ranged from 6 in case of Early White Jewel to 18 in case of Burt and 20 in case of Joanette. Joanette and Daubeney averaged 23.8 and 25.1 per cent, respectively, in hull percentage as compared with
Oats The Wheat Buckwheat Rye (Petkos) Spelt Emmer Wheat Wheat Oats

Field experiments, C. D. Woods (Maine Sta. Bul. 188, pp. 25-32).—In a test at the Highmoor Farm of 31 oat varieties, Silver Mine with a yield at the rate of 71 bu. per acre was excelled only by plots of Regenerated Swedish Select which yielded at the rate of 72.1 and 73.3 bu. per acre, respectively. The average yield of all varieties was at the rate of 64.2 bu. per acre and only one plot yielded at a rate less than 50 bu. Especial interest was attached to

The more notable yields secured in variety tests.

</table>
4 samples of Banner oats secured from widely separated sources. Two plats planted with seed from the Canadian Northwest (Coooldale, Alberta, and Creeelman, Saskatchewan) yielded about 5 bu. more per acre in each case than another plat planted with New Brunswick seed.

In a comparison of modified ridge culture and full ridge culture methods for potato growing in Aroostook County, the 3-year average yields secured were 273 and 283 bu. per acre, respectively. The author concludes that in the 3 years 1907–1909 there was "practically nothing to choose between the 2 methods so far as the yield was concerned in Aroostook County." The seasons of 1907 and 1909 were quite wet and that of 1908 was rather dry for high ridge culture.

Some soiling crops for Pennsylvania, T. I. Mairs (Pennsylvania Sta. Bull. 109, pp. 3-20, figs. 6).—The author presents a classification of soiling crops for the farmer's use as an aid in the selection of the crop best adapted to his conditions. A brief discussion is given of each of the crops thus classified and the results of experimental growings of many of them are stated.

The only vetch which gave promise of being useful in Pennsylvania was the hairy vetch. Orchard grass proved quite satisfactory as an early grass for soiling, but brome grass is not believed to be likely to take the place of the grasses already commonly grown. The following table states the highest and lowest yields and certain other data for the forage crops tested:

The harvest residues of cereals and field peas, B. Schulze (Fühlings Landw. Ztg., 59 (1910), No. 23, pp. 801–807).—Experiments made by the author showed that the air-dried weight of stubble and roots remaining after harvest amounted to 1,986 kg. per hectare (about 1,767.5 lbs. per acre) in the case of winter rye, 2,027 kg. per hectare from winter wheat, 2,110 kg. from oats, and 1,338 kg. from barley. The results secured for field peas were based on the calculation that 1 hectare would contain 300,000 plants, and under this assumption the quantity of air-dried residue after harvest would amount to 3,540 kg.
The weight of the kernel and its importance, H. Quante (Fühling's Landw. Ztg., 60 (1911), No. 1, pp. 1-28).—In this article the author discusses the absolute specific and volume weights of kernels of the common grains in their relation to each other and with reference to their value in determining the quality of the grain. It is pointed out that the absolute weight or the weight per thousand kernels is of the greatest importance, as it points out directly the development of the embryo and the quantity of reserve material contained in the kernel.

Methods of conducting variety tests, H. Scholz (Fühling's Landw. Ztg., 59 (1910), Nos. 22, pp. 776-785; 23, pp. 807-830).—The author discusses at some length the faultiness of ordinary methods of conducting variety tests and proposes means by which the possibility of error may be eliminated or much reduced.

Test of local and improved varieties of barley, G. Pummer and E. Freidl (Wiener Landw. Ztg., 61 (1911), No. 2, pp. 10, 11).—The results of variety tests carried on for 3 years are reported and discussed. It was found that while the local varieties gave good results, the improved varieties gave better results, and among these Loosdorf Thaya, Zaya, and Laa are mentioned as being especially promising.

Barley culture in Wisconsin, R. A. Moore and A. L. Stone (Wisconsin Sta. Bul. 212, pp. 3-17, figs. 7).—Discussions of the status and of classes of barley in Wisconsin and in the United States are followed by directions for barley breeding, growing, and marketing, and the prevention of smut.

Five years' tests reported by 1,020 members of the Wisconsin experiment association show that Oderbrucker barley gave a 5-year average in different parts of the State of 35.7 bu. per acre, or 4.9 bu. above that of the other varieties tested. At the experiment station the 10-year average for this variety was 50.7 bu., as compared with 28.7 bu. of the common barley secured by Wisconsin farmers, and 25.8 bu. for the United States as a whole.

The management of clover in corn belt rotations, J. A. Drake (Ohio Sta. Circ. 111, pp. 3-19, figs. 4).—This circular, prepared in cooperation with the Office of Farm Management of this Department, is based largely on conditions in the corn belt area of Ohio. A general discussion of the value of clover in rotations is followed by suggestions on rotations including various grain crops, including a description of benefits which have been noted from a light mulch for clover of straw or cornstalks.

Bird's foot clover or yellow trefoil (Lotus corniculatus) and its value as a pasture grass, H. Witte (Sveriges Utsådesför. Tidskr., 21 (1911), No. 2, pp. 106-110).—The author reports and discusses the results of trials of grass seed mixtures containing bird's foot clover. This clover appeared, in Denmark, to demand less lime in the soil than red clover and to be less sensitive to drought, outyielding red clover in dry seasons. It also outyields red clover on poor soils but should not be grown in cold or acid soils.

Increased yields of corn from hybrid seed, G. N. Collins (U. S. Dept. Agr. Yearbook 1910, pp. 319-328).—Similar discussions and data from the same author have already been noted (E. S. R., 24, p. 286). In work with first generation hybrids in sweet corn it was observed that "in 8 of the 10 hybrids the yield per plant exceeded the average of the parents, and in 6 instances it exceeded that of either parent. The average yield of all the hybrids compared with the average of the pure strain showed an increase of 57 per cent."

Of varieties and strains tested at Pullman the Flint variety Gehn, North Dakota White Flint, Rhode Island White Flint, and a Yellow Flint secured from Leland, Idaho, and the Dent varieties, Yellow Dent secured from Oakesdale, Wash., Yellow Dent from Pullman, Wash., Northwestern Dent, North Dakota Golden Dent, Dent secured from Myers Falls, Yellow Dent secured from Pullman, Wash., Minnesota King, and White Dent secured from Pullman, matured in about the order named. Minnesota No. 13, Bloody Butcher, and White Cap Yellow Dent did not mature at the station, but are regarded as promising varieties for the warmer and longer seasons of Walla Walla and similar localities.

Thayer Dent and Windus Dent were selected for improvement and distribution. They are briefly discussed as are also Minnesota King and certain other varieties tested. Cooperative trials of the Thayer and Windus varieties in 1910 indicate that a majority of the farmers reporting results from that part of the wheat region where the rainfall exceeds 15 in. were successful with these varieties, but that in the very dry belt a majority reported failures.

Some possibilities of the cowpea in Macon County, Alabama, G. W. Carver (Alabama Tuskegee Sta. Bul. 19, pp. 5-23, figs. 5).—Directions for the production and harvesting of cowpeas and a discussion of their value as food for man and animals are followed by directions for preparing numerous dishes from the cowpea previously noted (E. S. R., 20, p. 109), and notes as to diseases and insect pests.

Groundnuts in the Bombay Deccan, G. H. Kelkar (Dept. Agr. Bombay Bul. 41, 1911, pp. 17).—Tables report the area devoted to peanut growing in the Bombay Presidency, the average rainfall of the places where this crop is grown, and the exports, covering the past 14 years in each case. The author assigns as causes for the decline in acreage (1) the tikka disease due to Sceptridium arachidis, (2) unfavorable seasons, (3) the degeneration of seed due to improper cultural methods, (4) lack of proper rotation, and (5) failure to replenish the soil by the addition of manure.

An itemized statement of the cost of production and the returns per acre of peanuts indicates a profit of 37 1/2 per cent. In tests, fungicides gave negative results so far as the tikka disease was concerned. Newly imported varieties were attacked by the disease, but some promised to escape serious damage because of their early ripening period.

In a test of 5 varieties, Big Japanese and Selected Virginia produced the highest yields of 3,171 and 2,966 lbs. per acre, respectively. A table states the oil content, number of kernels per pod, and percentage of kernels to nuts of the original seed and the farm-grown crop of each of the 5 varieties.

In a rate of planting test the larger varieties were planted 12 in. apart each way and 12 by 9 in., while the smaller Spanish and Japanese varieties were planted 9 by 6 and 6 by 4 in. apart. Closer plantings produced the higher yields in case of every variety except Tata. The Spanish and small Japanese varieties stood highest in oil percentage and percentage of kernels. A table states the weight per acre of (1) roots, stems, and leaves; (2) shells of seeds; (3) kernels produced by each of the 6 varieties as well as the amount of nitrogen, phosphoric acid, and potash per acre produced by each of these 3 divisions of the plant, and the amount of oil per acre produced by the kernels.

Variety tests of oats, F. D. Gardner and J. A. Runk (Pennsylvania Sta. Bul. 108, pp. 3-14).—Yields in 1906, 1907, and 1908, previously noted (E. S. R., 23, p. 536), are reported, and also yields in 1909 and 1910.

In 1909 Japan oats yielded 63.4 bu. on its best plat as compared with corrected yields of 63.6 and 63 bu. respectively from Kherson and Jounette. In 1910 the highest corrected yield of grain was secured from the variety 453–06.
In a test of 8 varieties which averaged 13.6 per cent of smutted heads New Danish White appeared most resistant, with only 8 per cent smutted. Tables indicate the average yields secured from varieties that have been under test for periods of from 2 to 20 years, and give descriptions of 24 varieties.

Three years' cooperative tests of winter oats have resulted in failures in every county included in the test except for one report each from the counties of York and Chester. The author concludes "that winter oats are not adapted to Pennsylvania conditions, although in mild winters they may succeed in the southeastern portion of the State."

Field peas on a Palouse wheat farm, G. Severance (Washington Sta. Popular Bul. 36, pp. 4, fig. 1).—A general discussion of field peas under Washington conditions and directions for growing and harvesting the crop accompany a statement of the results of cooperative trials of seed distributed from demonstration trains.

Peas have been grown on the station farm every year since its establishment. The yields for which records have been kept range from 3.3 tons of cured hay per acre from Marrowfat peas and 4.2 tons from Canada field peas, and the grain yields from 9.3 bu. per acre of Canada field peas in 1909 to 38.5 bu. in 1903 of the same variety. The yield of 4.2 tons of hay per acre was secured on a rich north slope.

Productiveness and degeneracy of the Irish potato, C. L. Fitch (Colorado Sta. Bul. 176, pp. 16, figs. 8).—The author submits in this bulletin preliminary studies mostly within the Pearl variety, but he believes "that the principles true of one variety will be fundamental to all varieties of Irish potatoes." He indicates that certain plant and tuber characteristics are correlated and that the tuber and its parts are analogous to the stem and its parts, as shown by drawings of a tuber, an aerial tuber, and a plant stem. Early dryness, close and deep cultivation, and disease are indicated factors of the tendency toward seed bearing. "Tuber productiveness in Pearls is inversely proportionate to the sexual development of the plant."

The author describes 5 types or stages of Pearl vine degeneracy and states the tendency of each to appear under various local conditions. The same lot of seed from Del Norte produced only the better types when planted at Carbondale in 1910, but produced also the poorer types the same year at Greeley. Four year's hill selection at Greeley indicated that sexual tendencies are stronger than selection, as long, cylindrical and irregular shaped tubers and tendency to seed-bearing appeared in spite of selection to prevent these phenomena. Change from region to region or from farm to farm, if not to a richer soil, retards this development, thus maintaining to a degree the good tuber shape. "We find, however, that constant change may hold in suspension for several years the tendency to seed bearing and tuber degeneracy, which may then come suddenly on return to less favorable conditions, or on being grown for a second year on the same ground."

The author judges that incomplete fertilization is characteristic of the hybrid in Colorado of Rural pollen and of the pollen from the Early Rose family as 650 seed balls of this hybrid contained no seeds. Of 7 seed balls saved from crosses of Pearl and Rural at Del Norte 1 of Rural pollen on Pearl contained no seeds, while the 6 of Pearl pollen on Rural all contained abundant seeds.

The author defines the term "balance" "as the proper relative growth of the main stem, branches, and leaves and the proper relative influence indicated by aerial tubers to be exercised by each upon the shape of tubers formed by the swelling of underground stems."
Ten rules for the production and selection of "good Pearl seed potatoes" are given.

The potato and its culture, J. H. Shepperd and O. O. Churchill (North Dakota Sta. Bul. 90, pp. 83–126, figs. 12).—This bulletin gives directions for the production, harvesting, storing, and marketing of the potato crop, with notes on the controlling of diseases and insect enemies, a potato score card, and a plan of a potato cellar. Many of the suggestions are based upon the results of experimental work.

The use of a rotation consisting of a crop of potatoes followed by 3 crops of wheat resulted in an average annual increase of 3.3 bu. in the yield of wheat during the 12 years of the test. The grain crop secured, even in the least favorable seasons, equaled those following the best summer fallow. In 1900, wheat following potatoes yielded 24.3 bu. per acre as compared with 29 bu. after summer fallow, and 4.7 bu. after grain.

Large and small potatoes planted whole gave yields of 138.7 and 92.4 bu. per acre respectively as compared with 100.9 bu. per acre secured from plantings of pieces containing 2 eyes each. These are the averages of 3-year tests at each of the 3 substations. Twenty bu. more seed per acre was required with large uncut tubers than with the pieces containing 2 eyes each.

The potato industry of Colorado, C. L. Fitch and E. R. Bennett (Colorado Sta. Bul. 175, pp. 3–89, pl. 1, figs. 44).—This bulletin describes at some length the potato industry of Colorado and gives advice on different points to potato growers in that State, including data on soils, cultural methods, storage, including plans for potato cellars, potato standards as to quality, and on potato diseases. An article by S. A. Johnson (pp. 42–45), on Potato Insects, is also included.

Observations were made on the actual loss which resulted from poor stands and it is reported that hills on either side of a place where but 1 hill is missing make up one-half the loss as a result of their better development, and that where more than 1 hill is missing there are positive losses of yield except for the weight of one-half of 1 hill. Observations on the stand of the potato crop in relation to the yield and the quality of the crop were also made in different parts of the State, and the results are reported in tabular form with comments.

Study on the culture of the sugar beet in different countries, H. Pellet (Ann. Sci. Agron., 3, ser., 5 (1910), 1, Nos. 1, pp. 1–52; 2, pp. 81–141; 3, pp. 161–180, agens. 10).—The author reviews the industry of beet-sugar culture in different European countries at some length and shows, among other facts, that Germany and Bohemia have an average production of 30,000 kg. per hectare (about 13.35 tons per acre), and that the sugar content of the beet in Germany rose from 11 to 12 per cent for the years 1885–1890 to from 15 to 17.6 per cent for the years 1905–1908, inclusive. In Bohemia, the sugar content of the beet was gradually increased from 13.1 per cent in 1890 to 17.7 per cent in 1908. The average yield of sugar for the European sugar-beet growing countries has ranged for several years from 5,050 to 5,155 kg. per hectare. An increase in yield and in sugar content was also secured in Moravia, Silesia, Hungary, Sweden, Denmark, and Belgium, while in France the development along these lines was the least pronounced.

The formation of the sugars and starch in the sweet potato, T. E. Keitt (South Carolina Sta. Bul. 156, pp. 3–14).—Continuing previous work (E. S. R., 20, p. 1S1), this bulletin reports the results of analytical work upon sweet potatoes grown on clay soil in 1908 and sandy soil in 1909.

In 1908 the sugary varieties chosen were Purple Yam and Fulleton Yam, and the starchy varieties Nancy Hall and Polo. Samples were taken at 5 dates
ranging from August 28 to November 18. It is noted that wet cloudy weather prevailed during the 10 days preceding the taking of the first samples. In every case the first samples show higher starch percentages than the second samples while the latter had higher moisture contents, except in the case of the Fullerton Yam. Recalculation of the increased moisture to the moisture of the earlier samples would not account for the decreased starch content, which was in fact almost as great as the increase in water content. The author suggests 2 reasons for this condition: (1) That at this period of rapid growth some starch and sugar might be used in making cellulose of cell coverings, and (2) that as cells rapidly increase their size their water content also becomes greater. He also observes that the indications are that moisture content varies with the stage of growth irrespective of rainfall, and that the upward tendency of starch and low sugars continued until maturity or until freezing killed the vines. On August 28 sucrose was high and glucose low, but as maturity approached sucrose decreased and glucose increased, although both starch and total sugars decreased during the most rapid development. Later the starch increased, but water and total sugars decreased. On November 18, however, the sucrose was again high and glucose low.

In 1909 the work was continued with Purple Yam and Pumpkin Early Yellow Yam as sugary varieties and Polo and Brazilian as the starchy varieties.

As a general conclusion from the 2 years' work the author believes that in the immature potato sugar may be present either as glucose or sucrose, depending upon meteorological conditions, and that sucrose is formed as a product of the breaking down of starch as the potatoes mature. The 1909 crop grown on sandy soil was much higher in starch than the 1908 crop grown on clay loam. Where starch production is the object, if the plant is not evidently mature, it should be dug immediately after the first killing frost, as the highest starch percentage since the tubers have developed is then present.

Experiments in crossing turnips, J. H. Wilson (Trans. Highland and Agr. Soc. Scot., 5. ser., 23 (1911), pp. 18-31, figs. 8).—In a cross between the purple-top Swede (seed parent) and a yellow turnip, it was observed that there was a smaller number of seeds in the capsules than in those resulting from the fertilization of the Swede by its own pollen. The seeds “were distinctly smaller, being virtually like average turnip seed.”

When the hybrid seedlings developed, new characters in leaves and bulbs evidenced the success of the experiment. Twelve bulbs resembled closely the yellow turnip while 6 were purple-top. The neck was very short if present at all. The author attaches much significance to the presence “of irregular swellings on the roots and at the bases of the bulbs of certain of the plants, these swellings bearing a considerable outward resemblance to finger-and-toe disease.”

The flowers of the hybrids were intermediate in character and a very large proportion of the pollen grains were misshapen and abnormally small. The capsules were undersized and apparently absorbed only a small part of the resources of the plant, which used its reserve energy “in the development of a successive series of fine twigs, the latest of which were quite green and bearing flowers when the earliest capsules were ripe and the shoots that bore them were dead and dried.”

Irregularity in fruiting and serious deterioration in the form of the bulbs was observed in the second generation. The more closely the hybrid resembled the turnip the more liable it was to malformation by the counterfeit finger-and-toe disease. The author describes the second generation plants in detail and expresses the opinion that there is “little likelihood of such a strain as
was perpetuated in the experiments just described leading to useful commercial results."

He also reports the results of crosses with curled kale in which it was observed that the Swede-like crosses were the least diseased. The reciprocal crosses of turnips and Swedes in which the seed parent was the same as that used in the pollen parent in the series just discussed were traced for several generations, but "they varied in a fashion not to be distinguished from those of the crosses described in the foregoing pages."

Weeds in relation to soils, W. E. Brenchley (Jour. Bd. Agr. [London], 18 (1911), No. 1, pp. 18-24).—These pages report the results of observations on about 150 fields yielding 107 species of weeds of 74 different genera.

Thirty species representing 28 genera were each seen but once. A table states the frequency with which each of 36 of the weeds was observed on (1) clay and heavy soil, (2) chalk, and (3) sand and light loam. "While the nature of the soil plays such an important part in determining the local weed flora, the character of the crop, generally speaking, is a matter of indifference. The one exception to this rule is in the case of seed crops—clover, lucern, sainfoin, and trefoil."

In view of the fact that 6 species were found to be popularly designated as "twitch" or "couch" grass in different localities, the author suggests that it is advisable to apply the name "couch" to Triticum repens, only "designating as 'twitch' all other grass weeds of the characteristic habit of growth."

Special investigations indicate that colts-foot and horsetail, which are often found together, occurred indiscriminately on acid or alkaline soils, but could not be regarded as indicative or symptomatic, while spurrey (Spergula arvensis) "is very symptomatic of acid soils, and it often disappears entirely where lime is applied, reducing the acidity."

HORTICULTURE.

A new method of forcing plants, S. T. Parkinson (Jour. Southeast. Agr. Col. Wye, 1910, No. 19, pp. 245-257, pls. 3).—The various methods which have been experimented with in forcing plants are briefly noted, and demonstration experiments conducted at the Southeastern Agricultural College, Wye, Kent, to test the use of the warm bath method of forcing plants employed by Molisch (E. S. R., 23, p. 40) are described. The method was used with more or less success, but the results as a whole indicate the importance of knowing the best time for treatment in the case of any particular variety of plant.

In the experiments with rhubarb, in addition to the forcing stimulus noted, the treated plants gave a much larger yield. The latent effect of the bath was also illustrated, since the treated plants were not potted for 4 or 5 days after dipping.

In tests reported of spacing strawberry runners by hand instead of allowing them to find their places naturally, the yield from the hand-layered runners was about double that from the naturally-layered runners. The marked difference is attributed to the dryness of the season whereby crowded plants would suffer much more than those not crowded.

A trial of the overhead irrigating system with lettuce gave highly satisfactory results and indicates that in times of drought an artificial system of irrigation can be profitably used by the market grower.
As a result of tests conducted for a number of years, lists are given of varieti-
es of fruits and vegetables recommended for culture, together with the results
secured with indoor tomatoes during the past season.

3).—During the season of 1910 a number of annual truck crops adapted to
Colorado conditions were grown in the station gardens. Notes are herein given
relative to the behavior of the different vegetables grown and their adapta-

Considerable trouble has been experienced in the reversion of selected cab-
bage seed to original types. From breeding experiments conducted by the
station in 1908-9 the possibility of procuring certain plants with fixed char-
acteristics, in accordance with Mendel’s law, was indicated.

Production of a white bean lacking the factor for total pigmentation—a
prophecy fulfilled, R. A. EMERSON (Amer. Breeders’ Assoc. [Proc.], 6 (1909),
pp. 396, 397).—In continuation of his studies relative to the inheritance of
color in the seeds of the common bean (Phaseolus vulgaris) (E. S. R., 22,
p. 40), the author has been successful in producing a white bean without the
total pigmentation factor. The results are briefly discussed.

Cultural experiments with cabbage in 1910, HUBER ET AL. (Mitt. Deut.
results are given of cooperative variety and cultural tests of cabbage conducted
under the direction of the German Agricultural Society in 1910.

The manurial constituents taken from the soil by an average crop of
(1910), pp. 102, 103).—The analytic results and conclusions are given of a
study of the above subject made by J. F. Harries.

Figuring on a yield of 5 tons of heads per acre, the total fertilizing ingredi-

ents in the heads, leaves, and roots were phosphoric acid 36.5 lbs., potash 88.3
lbs., nitrogen 116.5 lbs., and lime 94.3 lbs. The heads, which are generally the
only part removed from the soil, contained phosphoric acid 10.2 lbs., potash
24.5 lbs., nitrogen 33.9 lbs., and lime 6.7 lbs. These figures as compared with
figures for various crops given by Hopkins (E. S. R., 23, p. 17) indicate that
cauliflower is a relatively light feeder.

The cultivation, production, preparation, and utilization of castor seed
(Bul. Imp. Inst. [So. Kensington], 9 (1911), No. 1, pp. 17-35).—A general
account including information relative to experimental plantings made in
British territory.

Experiments on the storage of onions (Agr. News [Barbados], 10 (1911),
No. 238, p. 191).—The results are given of certain experiments on the storage of
onions, conducted during 1910 at the Antigua Experiment Station with a
view of finding some means of carrying the local crop over periods of the year
when onions are not in season, and for the purpose of furnishing large bulbs
for planting the local crop, it being necessary at present to raise the crop from
sets. Twelve onions were used in each test. One lot was dusted with slaked lime,
another with flowers of sulphur, and others were treated with carbon
dioxid gas, Bordeaux mixture, 1:1,000 corrosive sublimate solution, and sulphur
dioxid gas, respectively. The onions were stored in a well-ventilated room
and examined at different intervals from April to October, inclusive. None of
these methods of treatment materially affected the rate of decay of the bulbs,
although the flowers of sulphur seemed to have some slight beneficial action.

No advantage was gained by stringing the onions together.

Observations on the blossoming of our hardy cultivated fruits, C. H.
3).—Comparative data, collected at Wye, Kent, are given showing the average
date of commencement, full bloom, and duration of bloom of a large number of varieties of plums, pears, and apples. Similar data are given for cherries as well as for various small fruits.

Selecting an orchard site, N. O. Booth (Oklahoma Sta. Circ. Inform. 13, pp. 4, fig. 1).—A brief popular discussion.

Notes on a dry-land orchard, J. E. Payne (Colorado Sta. Bul. 173, pp. 3–7, figs. 6).—A small orchard consisting of cherry, plum, and apple trees, together with gooseberry plants, was established at the Plains Substation at Cheyenne Wells, in 1894. Forest trees were planted for windbreaks around the orchard and along the north side of the farm. Brief notes are given on the history, behavior, and condition of the trees in this orchard when inspected during the past year.

Although this is one of the best dry-land orchards in eastern Colorado, its history as a whole shows that the apple trees in particular have needed extra water at some time during each year since they began bearing fruit. The cherry and plum trees produced good crops without extra water nearly every season, but would also have been benefited by additional water. The goosberries bore well until neglected.

It is pointed out that nearly all settlers plant more trees than they find time to care for and consequently lose all. The dry-land orchard is not considered a commercial proposition, but the planting of a few well-selected trees which may be given extra care is recommended. Where trees are used for windbreaks, the history of the orchard has shown that they should be planted at least 100 ft. from the fruit trees.

An examination of the roots of 4 apple trees dug up in August, 1910, showed that nearly all the large roots were in the first 12 in. of soil. The roots of these trees grew deeper when the soil was wet below the normal depth. The growth of nursery-grown trees which were planted from 2 to 2½ ft. deeper than in the nursery was not decreased nor was the position of the feeding roots materially altered.

Thinning the Winesap.—Winter and frost injuries of fruit trees, R. S. Herrick (Colorado Sta. Bul. 170, pp. 19, figs. 3).—The first section of this bulletin reports an experiment in thinning Winesap apples conducted in 1910, discusses the advantages of thinning, and gives directions for it. The remainder of the text comprises a discussion of the nature of winter injuries of young and old trees and of spring frost injuries, together with suggestions for the prevention of frost injuries in general.

The fruit of 6 Winesap trees was thinned about June 16, or shortly after the June drop, 2 other trees were thinned on July 22, and 2 unthinned trees were used as checks. The average results showed a gain of $1.85 per tree for the thinned fruit. The thinned trees yielded an average of 12.72 boxes, of which 5.34 were extra fancy, 3.07 extra choice, 3.2 standard, and only 1.11 total culls, as compared with an average of 17.58 boxes on the unthinned trees, of which only 2.5 were extra fancy, 1 extra choice, and 9 standard, with 5.08 boxes of culls. In this experiment late thinning was just as advantageous in improving the quality and increasing the quantity of high grades as early thinning. Early thinning is recommended, however, in order that the remaining fruit may develop quicker and the vitality of the tree be conserved.

Protecting trees from rabbits, D. C. Mooring (Oklahoma Sta. Circ. Inform. 14, pp. 3, fig. 1).—A popular circular describing the protection of trees from rabbits by means of trapping, poisoning, tree protectors, and washes.

Orchard spraying problems and experiments: A review of and a contribution to previous data, W. W. Bonns (Maine Sta. Bul. 189, pp. 33–89, pls. 12, figs. 10).—This bulletin contains a review of the literature of orchard spray
injury and of the substitution of lime-sulphur for Bordeaux in combating fungus diseases, together with a report of a comparative test of various lime-
sulphur solutions and Bordeaux conducted by the station at the Highmoor
farm in 1910. Lead arsenate was used with each mixture and studied both
as to its insecticidal value and as to its relation to possible leaf and fruit
injury when used with lime-sulphur.

The spraying was done in a Ben Davis apple orchard, this variety being
especially susceptible to spray injury. Weather conditions during and follow-
ing the period of the second application were conducive to spray injury.
More or less injury was found on all of the plats, and the unsprayed fruit also
suffered severe russetting and malformation. The foliage injury on the lime-
sulphur plats was of little consequence, but was about 25 per cent more severe
on the Bordeaux plats. Fruit injury was from 2 to 5 times greater on the
Bordeaux plats.

Fruit sprayed with lime-sulphur showed two kinds of injury, one form of
which was similar to but less severe than Bordeaux injury. The other form,
which is attributed to the arsenical used with the sulphur spray, occurred with-
out exception at the calyx end and is designated as calyx injury. This injury
was first observed when the fruit was about one-third full size as a fairly
regular and circular dark brown discoloration surrounding the sepals and
about 1 cm. in diameter. As the season advanced it became blacker but did
not spread. In rare cases the injury extended well into the basin, was irregu-
lar in outline and confined to one side of the calyx. It was invariably accom-
panied by a bright carmine aureole upon the edge of the basin, the aureole
disappearing with the growth of the fruit. The injured skin frequently showed
a tendency to separate and curl away slightly from the normal skin adjacent.

The results of one season's work confirm the consensus of results elsewhere
secured as to the fungicidal value of the lime-sulphur mixtures. With weather
conditions favorable to spray injury lime-sulphur did less damage than Bor-
ddeaux, both qualitatively and quantitatively. Arsenate of lead proved equally
effective with lime-sulphur and with Bordeaux but was decidedly injurious
when used with Sulfoide. A neutral lead arsenate is recommended in order
to reduce the tendency to arsenical injury.

Both homemade and commercial lime-sulphur mixtures as substitutes for
Bordeaux are recommended for trial by Maine fruit growers, and directions are
given for preparing the mixtures.

Expt. Farm, 36 (1910), p. 31).—A summary is given of the general results
secured in tests of homemade and commercial lime-sulphur wash in concen-
trated form and used in conjunction with arsenicals. The results are based
upon tests made in the college and elsewhere in the Province.

Concentrated lime-sulphur, whether homemade or commercial, was found to
give excellent results as a spring wash just before the buds burst. It controls
blister mite, San José scale, and oyster-shell scale satisfactorily, is just as
good a fungicide as Bordeaux in the spring, and when properly diluted for a
summer spray will control apple and pear scab apparently as well as Bordeaux.
It sticks to the foliage and fruit about as well as Bordeaux and when diluted
about 1:35 is as cheap. Combined arsenate of lead and lime-sulphur gives as
satisfactory results as the 2 sprays used separately and there is apparently less
danger of injury to the foliage than from the lime-sulphur alone. Either
arsenite of lime or Paris green combined with lime-sulphur is apt to cause
serious injury to the foliage and sometimes to the fruit, especially when spray-
ning for the codling moth and in later sprays.
Lime-sulphur, its use as a fungicide and an insecticide, P. J. O’Gara (Medford, Ore., 1911, pp. 31).—A popular pamphlet dealing with the history and use of lime-sulphur solution, and prepared especially for the fruit growers of Rogue River Valley.

Spray calendar, A. L. Lovett (Oklahoma Sta. Bul. 92, pp. 3–16).—This bulletin contains popular information relative to spraying machinery, spray solutions, dust sprays, and other insecticides, together with a spray calendar covering most of the common troubles of fruits, shade trees, and vegetables.

Spraying calendar for 1911, R. K. Beattie and A. L. Melander (Washington Sta. Popular Bul. 33, folio).—The calendar includes directions for the control of the more important diseases and insects attacking fruits and vegetables, together with directions for preparing sprays.

Promising new fruits, W. A. Taylor (U. S. Depl. Agr. Yearbook 1910, pp. 425–436, pls. 8).—In continuation of similar articles (E. S. R., 23, p. 143), historical notes with descriptions and colored plates are given of the following new and little-known fruits that are considered worthy of more extensive trial: Lowry and Kinnard apples, Payne peach, Hoosier raspberry, Dugat orange, Family avocado, Cecil mango, and the Tamopan persimmon.

Commercial apple orcharding in Ohio, H. A. Gossard (Ohio Sta. Circ. 112, pp. 3–13, figs. 13).—In order to determine whether the results secured in previous spraying tests (E. S. R., 21, p. 352) might be considered as representative or as exceptional, and also to determine what combinations of sprays were best suited to Ohio conditions, cooperative spraying demonstrations were conducted by the station in 1909 in several different localities of the State. The quantitative records secured with some of these orchards are given, together with recommendations as to spraying procedure supplemental to those issued in previous publications of the station (E. S. R., 25, p. 39).

The Colorado raspberry industry, R. S. Herrick and E. R. Bennett (Colorado Sta. Bul. 171, pp. 3–16, figs. 4).—This bulletin deals with raspberry culture with special reference to Colorado conditions. It discusses the soil, climatic, and moisture requirements of raspberries, the preparation of the plantation, varieties, propagation, planting, cultivation and irrigation, winter protection, pruning, general management, yields, harvesting, possibilities of the industry, and diseases.

The mango in Florida, P. H. Rolfs (Proc. Amer. Pomol. Soc., 1911, pp. 34–49).—A brief statement of the progress made in mango culture in Florida, including descriptions of the different types of mangoes now grown there.

The precooling of fruit, A. V. Steenrauch and S. J. Dennis (U. S. Depl. Agr. Yearbook 1910, pp. 437–438, pls. 5).—The purpose of this paper is to present in a conservative and concise form the progress and results of the investigations which have been made by the Bureau of Plant Industry and to give the exact status of the process as far as it has been applied under commercial conditions. See also a previous note (E. S. R., 24, p. 641).

Cooperation among fruit growers, W. H. Chandler (Missouri Sta. Bul. 57, pp. 3–58, figs. 6).—This bulletin discusses and illustrates the growth of cooperation among fruit growers of the United States and Canada during the past few years and gives a list of 54 organizations, together with the constitution and by-laws of several. Some of these handle more than $1,000,000 worth of fruit in a year and some nearly $50,000,000 worth.

In the experience of 54 associations reporting, the principal benefits derived from cooperation are found to be as follows: “(1) Enabling the small growers to ship in car lots; (2) distributing the crop so as to prevent gluts in the markets; (3) enabling the growers to establish a brand that will be known and sought in the markets, thus insuring better prices; (4) making possible
better business methods in dealing with the fruit buyers, transportation companies, etc.; (5) enabling a community to make use of varieties of fruit that for any reason might not be desirable except in small quantities; (6) better equipment for handling the crop for a section; (7) insuring better care of the orchards; and (8) giving greater general business stability.”

Cooperation in the handling and marketing of fruit, G. H. Powell (U. S. Dept. Agr. Yearbook 1910, pp. 391-406).—The author shows the wide development of the cooperative fruit marketing idea in this country, points out the fundamental principles of cooperation, and discusses the organization and management of cooperative associations. A short account is also given of the organization of the citrus-fruit industry of California.

The existing duties on fruit as compared with the future new tariff agreement (Deut. Obstbau Ztg., 1911, No. 12-13, pp. 205-220).—This consists of a review of the existing tariff on various classes of fruit shipped into Germany from European and other countries, and an examination of proposed tariff agreements, with special reference to their influence on the development of native fruit industries in Germany. The statistics also include the German imports and exports of fruit for the years 1900 to 1909, inclusive, both by varieties of fruit and by exporting countries.

Notes on soil and plant sanitation on cacao and rubber estates, H. H. Smith (London, 1911, pp. LII+632, figs. 108).—This work comprises as a whole a résumé of information gleaned by the author from numerous practical planters, men of science, directors of agriculture, and others actually engaged in planting up and developing the Tropics, relative to the treatment of the soil, plant diseases, and pests. A number of tropical authorities have directly contributed to the book.

The successive chapters in part 1 discuss estate sanitation and hygiene, protective belts, stump pulling, manuring cacao, hygiene in cacao planting, the importance of nitrogen as a plant food, manuring cacao in Cuba, the manurial requirements of rubber trees, green manuring, preparation of plant foods from waste products, inoculation as a cure for pests and disease, the treatment of tropical plants, fungi pests, general pests, cacao diseases and pests, cacao beetle, and grafting cacao. Part 2 deals principally with rubber and discusses rubber on the Gold Coast, tapping rubber, rubber diseases, the culture and management of Castilla and Ceara rubber, wild versus cultivated rubber, plowing, soil sanitation by means of disk plows, the destruction of pests, cork insulation for estate buildings, rat extermination, rubber machinery, vacuum drying for rubber, cacao, copra, etc., the drying of cacao, and tapping knives and estate supplies.

Camphor cultivation in the United States, S. C. Hood and R. H. True (U. S. Dept. Agr. Yearbook 1910, pp. 449-480, pls. 3).—General consideration is given to the camphor industry as a whole, present methods of manufacture, and the cultivation of camphor in the United States as an ornamental. With the results of cultural experiments being conducted in Florida by the Bureau of Plant Industry as a basis, suggestions are given for the commercial cultivation of camphor trees in the form of hedges, including methods of harvesting and distillation.

Thus far the camphor industry in the United States is in an experimental stage, and no definite information has been secured relative to the yields and profits to be expected. At the present time it is not considered advisable to plant camphor in small areas with the hope of securing profitable earnings by selling the trimmings to a near-by distilling plant.

work for the year, together with lists of the more desirable ornamental shrubs, hardy roses, gladioli, geraniums, and annuals based on tests conducted on the college grounds.

Trees and gardens.—Hints on the cultivation of trees, flowers, and vegetables, and on the general improvement of school grounds (Ed. Dept. Victoria Circ. Inform. 16, 1911, pp. 24, figs. 16).—This circular comprises a number of articles, chiefly by Victorian writers, containing information on the above subjects.

Permanent lawns for the South, C. C. Newman (South Carolina Sta. Bul. 157, pp. 3–14, figs. 6).—Experiments were begun at the station in 1899 to determine what grasses were best suited for permanent lawns in the South. Out of 35 varieties of grasses and clovers sown on plats 20 by 30 ft., only Kentucky blue grass, Bermuda grass, herd’s grass, and white clover were retained after the third year as being suitable for permanent lawns. Kentucky blue grass, Bermuda grass, and white clover were again tested on different types of soil and exposure. The results of these subsequent tests which extended over a period of 9 years are here given.

Previous to establishing the plats the land was sown in peas in May, the vines being cut for hay in September and the pea stubble turned under. Six tons of thoroughly composted manure and 300 lbs. of lime were applied per acre before the land was plowed. Six hundred lbs. of a fertilizer analyzing 8 per cent phosphoric acid, 4 per cent nitrogen, and 5 per cent potash were subsequently incorporated with the soil by harrowing. The seed was sown the first week in October. Nitrate of soda at the rate of 75 lbs. per acre was applied to each plat each year about the middle of March. The results show that Kentucky blue grass when used alone thrives best on a clay or a clay-loam soil, yet when sown on sandy-loam soil with good clay subsoil and with a northern exposure it does well, provided the seeds are sown in the early fall. The plants from spring-sown seed do not become well established before the hot, dry weather, and frequently much of the grass is dead by fall.

Kentucky blue grass and Bermuda grass make a good lawn when grown together. The Bermuda grass predominates in the light soils and warm exposures and the blue grass on northern exposures. On red clay with clay subsoil with an open exposure both grasses have been growing together for 9 years, neither one being able to crowd out the other. In all cases this mixture has crowded out crab grass after the second summer. Mixtures of Kentucky blue grass and white clover and of Kentucky blue grass, white clover, and Bermuda grass grown with an open exposure on red clay with clay subsoil have also made good lawns. The addition of the white clover seems to be beneficial both to the blue grass and the Bermuda grass. The results as a whole indicate that a mixture of Kentucky blue grass and Bermuda grass is well adapted to partially shaded lawns.

When neither blue grass nor white clover can be grown successfully, Bermuda grass is recommended as one of the very best grasses for a lawn. For large lawns around country homes or in large groves where a coarse grass is not objectionable, a mixture of orchard grass and red clover is suggested. For a quick temporary lawn, Italian rye grass has proved very successful.

Color inheritance in the petunia, V. V. Westgate (Amer. Breeders’ Assoc. Proc., 6 (1909), pp. 359–362).—Some data are given covering the F1, F2, and F3 results of color studies which the author is conducting with the bell portion of petunia flowers.

FORESTRY.

Forest conditions in Illinois, R. C. Hall and O. D. Ingall (Bul. Ill. State Lab. Nat. Hist., 9 (1911), Art. 4, pp. 175-253, pls. 17, fig. 1).—This report is based upon a cooperative study undertaken by the Forest Service of this Department and the Illinois State Laboratory of Natural History. It discusses in detail the soil areas and forest types of southern and of northern Illinois, the distribution of tree species, including a list of 120 trees native to Illinois, the ownership and taxation of forest lands, and the various timber industries of the State. Suggestions are then given relative to the general methods of forest management, and to management for special objects and of various forest types. The question of forest protection is also discussed.

The investigation shows in brief that there are nearly a million acres of forests in the 26 counties estimated, most of which are more suitable for timber production than for agriculture. The woodlands are nearly all divided into small tracts and owing to their poor silvicultural condition their productive capacity is much below normal. It is recommended that the State adopt a progressive forest policy to be administered through a nonpartisan board of forestry and a technically trained state forester. The chief features of the policy consist in the adoption of an adequate state fire protection system, the inauguration of an educational campaign, and further investigations of the problems involved in developing and extending Illinois woodlands. A proposed forest law embodying the above policy is presented.

A bibliography relating to forest conditions in Illinois is appended

Report of the state forester, S. N. Spring (Connecticut State Sta. Rpt. 1909-10, pt. 11, pp. 775-804, pls. 3).—Aside from a brief statement relative to the various lines of work being undertaken, this report deals wholly with the subject of forest fires, especially with those of 1910. The phases considered include the fire warden service, statistics of forest fires in 1909 and in 1910, measures of control and prevention of forest fires, enforcement of forest laws, economic results of forest fires, statistics by towns, and a list of the town fire wardens in 1911.

Report of the professor of forestry, E. J. Zavitz (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 36 (1910), pp. 269-273, figs. 6).—This is chiefly a progress report on the reclamation of waste land and forest nursery operations at the forest station in Norfolk County. A table taken from the Ontario Bureau of Industries report for 1908 is given showing the percentages of woodland and slash land in the various counties of southwestern Ontario.

Reports on the forest administration in Burma for the year 1909-10 (Rpts. Forest Admin. Burma, 1909-10, pp. 3+9+II+195+9).—This consists of the usual progress reports on the administration of the state forests of the Pegu, Tenasserim, Northern, and Southern Circles of Burma for the year 1909-10. The more important data relative to forest reserves, settlement, surveys, working plans, forest offenses and protection, plantations, and other miscellaneous work, revenues, expenditures, etc., are appended in tabular form.

Micrography of the woods of Javanese trees, J. W. Moll and H. H. Janssonius (Mikrographie des Holzes der auf Java vorkommenden Baumarten Leyden, 1911, vol. 2, pt. 3, pp. 161-540, figs. 49).—This is a progress report on the study of the wood anatomy of Javanese trees which the authors have conducted since 1903. Some 100 additional species are described along the lines previously noted (E. S. R., 20, p. 1134).

Chaparral.—Studies in the dwarf forests, or elfin-wood, of southern California, F. G. Plummer (U. S. Dept. Agr., Forest Serv. Bul. 85, pp. 48, pls. 8, figs 7).—This bulletin comprises a study of the chaparral region of southern
California, including suggestions for its management and improvement. Consideration is given to the distinguishing characteristics of the true chaparral as compared with the dwarf trees and brush growth found in other arid sections of the United States, historical records of past forest conditions in the chaparral region, geographic conditions in the chaparral area, chaparral and the water supply, vertical range of chaparral, composition by species, amount of shade produced, value of the different species, representation of desirable and undesirable species on the Tujunga and San Gabriel watersheds, commercial uses, protection against fire, restocking after fires, and the introduction of larger tree species in the chaparral.

At the present time the chaparral is chiefly of value as a protection for watersheds. It also furnishes materials for fencing and for browsing of cattle, sheep, and goats when pasturage is scarce and for bee pasturage. A study of the existing conditions leads to the conclusion that larger tree species can be made to take possession of the chaparral regions by artificial extension alone. Experimental planting operations thus far made by the Forest Service and others have only been partially successful and indicate that the task will require patience and a thorough knowledge of the best planting methods.

The management of second-growth sprout forests, H. S. Graves (U. S. Dept. Agr. Yearbook 1910, pp. 157-168, pls. 2).—This article deals particularly with the management of young stands of hardwood in the Northeast which have come up after the removal of the virgin forests or of a subsequent forest. Certain broad principles of handling second-growth hardwoods are considered under the following general headings: Simple coppice or sprout system, holding over reserve trees, sprouts and standards, handling older sprout stands, and improvement cuttings.

Treatment of artificial tree plantations, E. Secrest (Ohio Sta. Circ. 110, pp. 21, figs. 16).—The cultural treatment of tree plantations is briefly discussed, special attention being given to the pruning requirements of different species. A number of illustrations accompany the text.

Fire prevention and control on the National Forests, F. A. Silcox (U. S. Dept. Agr. Yearbook 1910, pp. 413-424, pls. 6).—In this article general consideration is given to the importance of fire protection, the character of the region to be protected, economic losses, and the causes of fires. Various methods of fire prevention and control as employed in the National Forests are then described.

Progress in saving forest waste, W. L. Hall (U. S. Dept. Agr. Yearbook 1910, pp. 255-263, pls. 3).—In this article the author points out how forest waste occurs, shows a number of ways in which the waste is being saved, and suggests further methods of cutting down the loss.

National problems affecting the lumber industry (Rpt. Nat. Lumber Manfr. Assoc., 9 (1911), pp. 278).—This is an official report of the ninth annual convention of the National Lumber Manufacturers Association, Chicago, 1911, including papers and discussions on a number of problems affecting the lumber industry.

Rubber and gutta-percha, E. Tassilly (Caoutchouc et Gutta-percha. Paris, 1911, pp. XVIII+395+XII, figs. 56).—A handbook of information dealing with the history of the rubber industry, preparation and treatment of crude rubber, vulcanization, etc. The concluding chapters contain a chemical study of rubber and gutta-percha, together with analyses of the crude and manufactured products as determined by various methods.

The germination of Hevea seeds (Agr. News [Barbados], 10 (1911), No. 233, p. 111; Agr. Bul. Straits and Fed. Malay States, 10 (1911), No. 6, pp. 192-194).—The results are given of experiments conducted by G. G. Auchinleck in
Grenada to determine the cause for the low percentage of germination of the seeds of *Hevea brasiliensis*.

The investigation shows that all light seeds should be rejected in making selections for plantings. Seeds which were kept in the air lost 6 per cent of their weight in 2 weeks' time, whereas seeds packed in dried charcoal lost 20 per cent of their weight, the latter being about the extreme limit of desiccation. The loss of weight appears to coincide with loss of germinating power and desiccation apparently takes place in some instances even before desiccence of the capsule. It appears that without special precautions *Hevea* seeds will lose their germinating power within 2 or 3 weeks after the ripening of the capsules. It is considered important that no *Hevea* seed should be sold until it has been selected rigorously by weight, nor should any unnecessary exposure or loss of time in planting be allowed.

Ceara rubber (*Bul. Imp. Inst. [So. Kensington], 9 (1911), No. 1, pp. 1–8*).—Analyses based on examinations made by the Imperial Institute are given of specimens of Ceara rubber from Ceylon, Uganda, East Africa Protectorate, Nyasaland, Sudan, and Southern Nigeria.

**DISEASES OF PLANTS.**

Report of the botanist for 1909 and 1910. G. P. Clinton (*Connecticut State Sta. Rpt. 1909–10, pt. 10, pp. 713–774, pls. 8*).—This report includes notes on diseases in relation to weather in 1909 and 1910, new observations on diseases previously reported, diseases or hosts not previously reported, spraying potatoes in dry seasons, and a study of the formation of the oospores of potato blight (*Phytophthora infestans*).

The following diseases were found to be prevalent or unusually severe during 1909: Black rot, rust, scab, and spray injury on the apple; rust on the ash; bark disease on the chestnut; wilt on the eggplant; leaf spot on the elm; leaf mold and anthracnose on the muskmelon; brown rot (on twigs) and leaf curl on the peach; black knot on the plum; tip burn and scab on the potato; leaf blight on the quince; rust on the rose; leaf mold on spinach; powdery mildew and winter injury (to roots) on the strawberry; and calico on tobacco. During 1910 the following diseases were noted: Rust, scab, frost, and spray injury on the apple; black knot on the cherry and plum; bark disease and drought injury on the chestnut; smut on corn; rust on the hollyhock; leaf scorch on the maple; mildew blight on the muskmelon; leaf curl and brown rot (of twigs) on the peach; scab on the pear; pine-sweetfern rust on the pine; rot (blight) and tip burn on the potato; powdery mildew on rye and barley; rust on the quince; and anthracnose on the sycamore.

It is claimed that successive droughts for the past 4 years have affected the forest trees, especially pines and chestnuts, making the latter more susceptible to the chestnut bark disease, and also that the unusual winter of 1904 seriously injured the chestnuts so that the bark disease fungus (*Diaporthe parasitica*) became actively parasitic. Theured and teleutospore stages of *Pucciniastrum myrtilli* (*Peridermatum peckii*), the hemlock-heath rust, is reported on various species of blueberries and huckleberries. In discussing the so-called blight of the white pine, the author claims that it is due primarily to adverse weather conditions, such as winter, drought, and frost injuries. Specimens of *D. parasitica* have been collected on the Japanese chestnut (*Castanea japonica*) in a local nursery, and are also reported on *C. sativa* and *C. pumila*. The pine-sweetfern rust (*Cronartium comptonae*) is reported on *Pinus rigida*, *P. austriaca*, and *P. maritima*. The pine-currant rust (*Cronartium ribicola*), which
had been reported from several localities in the State on white pine seedlings, has been apparently eradicated.

The results are given of potato spraying experiments with Bordeaux mixtures, in which the influence of the character of the fertilizer (stable manure v. nitrate of soda) used, the system of cultivation (ridged or flat), and the effect on the late blight and scab of the potato of growing successive crops of potatoes on the same land are investigated. The benefits other than fungicidal derived in a dry season from the use of Bordeaux and arsenate of lead sprays are believed by the author to be due to the conservation of moisture in the leaves during dry seasons by clogging the stomata and water pores with the sediment of the spray. Details are also given of experiments in spraying conducted during 1906, 1907, 1908, and 1909. In both wet and dry years increased yields were obtained by spraying with a 4 : 4: 50 Bordeaux mixture.

The author describes in detail studies on the formation of oospores of the potato blight, including media used, variability of oospore production, microscopic characters of the oospores, and hybrids, a preliminary account of which has been previously noted from another source (E. S. R., 25, p. 348). The best culture medium for the production of oogonia, anthridia, and oospores was found to be an oat-juice agar prepared as follows: Fifty gm. of ground oats mixed with from 300 to 350 cc. of water was cooked for 30 minutes in a covered dish with steam from an autoclave run in by means of glass and rubber tubing, and after straining the coarser materials off, 10 gm. of agar was added and the mixture steamed for another 30 minutes. The mixture was then brought up to 500 cc. by adding water if necessary, poured into test tubes, and sterilized for 15 minutes under from 7 to 10 lbs. pressure. This was the only medium in which the author was able to obtain perfectly developed and mature anthridia and oospores. It was also found that the best condition for oospore production is between neutrality and 15 cc. acidity of the medium.

**Fungi and plant pathology**, S. B. McCready (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 36 (1910), p. 37).—A report is made on the diseases examined during the year, and on experiments for the control of black rot of the apple (Sphaeropsis malorum). The characteristics of stinking smut and loose smut of grain are given, together with a brief description of the accepted methods for combating them.

**Four little-known British fungi**, W. B. Grove (Jour. Econ. Biol., 6 (1911), No. 2, pp. 38-49. pls. 2, fig. 1).—Descriptions are given of Mucor spinosus, which ferments glucose but not sucrose, of M. spinosus recurvus, of Rhopalocystis nigra, which is a convenient source of invertase and emulsin, of Monilia lupuli found on the surface of spent hops when exposed in heaps to the air, and of Hormodendron cladosporoides.

The article closes with a brief discussion of the differences between certain species of Hormodendron and closely related Penicillium species.

**Studies on Corticium javanicum**, A. Rant (Meded. Dept. Landb. [Dutch East Indies], 1911, No. 13, pp. 38, pls. 7).—In a general study of this fungus the author cites its known hosts, gives its distribution, describes the characteristics of the disease, and gives the results of inoculation experiments with the fungus from various hosts and localities, methods of infection, and means of combating the disease.

crotica, Plunaria acutifolia, Thephrosia purpuca, Polygonum chinense, De-
brocasia longifolia, Raucofia javanica, Cypholophus lutescens, Lantana
samarum, Erizobotrya japonica, Melochia indica, Dombeya wallichii, Eu-
patorium lanthinum, Diospyros kaki, Claroxyton indicum, Macropanax oreophilum, Ho-
malanthus populatus, Urena tomentosa, Saauria spp., Trecma orientalis, Eu-
calypytus saliva, Cassia spp., Cedrela sinensis, Cestrum aurantiacum, Lantus
domesticum, Artocarpus integrifolia, Orthosiphon staminicus, Gardenia florida,
Sesbania aegyptiaca, Clerodendron macrospiphon, Cupressus glauca pendula, Stachyta-
rapheta dichotoma, Allamanda hendersoni, Hibiscus spp., and Nervium oleaceus.

Four forms of the disease are given, viz, (1) the typical fruit-bearing form of
C. javanicum, (2) whitish, knot-like rhizomorphs, (3) white, glistening, cobweb-like fungus threads called the cobweb mycelium, and (4) the Necator
decrctus form. It is claimed that the general method of infection is as fol-
lows: First, the spores of Corticium or Necator fall on a branch. These spores
on germination form the cobweb mycelium stage in which the fungus lives
as a saprophyte. From this develops the knot-like rhizomorphs, which finally
infect the living tissues of the host, followed eventually by the fruiting form
of Corticium and Necator, by which time the attacked portion is usually dead.
From cross-inoculations with the different forms of this organism on various
hosts, the conclusion is reached that the cobweb mycelium, the knot-like rhizo-
morphs (sclerotia), and N. decretus are but different stages in the life history
of C. javanicum.

Col. and Expt. Farm, 36 (1919), pp. 163-165, figs. 3).—In a report on pear
blight, prepared by D. H. Jones, it is claimed that this disease has been prevalent
on both apple and pear trees, but not so seriously as last year. In one
young orchard trees were found which had been inoculated with the disease
by the buffalo tree hopper to such an extent that twigs, limbs, and bark were
all badly infested. The characteristic slit punctures of the tree hopper were
found in rows on the trunks of the young trees, and from these punctures the
disease had spread until in some cases the tree was completely girdled and
killed. In another orchard conclusive evidence was found that the shot-
hole bark-boring beetle (Scolytus rugulosus) was a carrier of the blight, as
many of the trees had shot-hole borings around which the blight had extended
producing the characteristic blight cankers.

A leaf spot (Pseudopeziza medicaginis) of alfalfa is also discussed and de-
scribed.

Rhizoctonia medicaginis in America, F. D. Heald (Phytopathology, 1
(1911), No. 3, p. 103).—Attention is called to previous notes on the occurrence
of this disease in America (E. S. R., 18, p. 244; 20, p. 437), and a brief de-
scription is given of the symptoms of the disease and the damage done by it in
an infected alfalfa patch in Nebraska.

New hosts for Sclerospora macrospora, G. Severini (Staz. Sper. Agr. Ital.,
43 (1910), No. 10, pp. 774-786, pls. 2).—The hosts listed are as follows:
Hordeum vulgare, Tricticum sativum, Avena sativa, Festuca elatior, Alopecurus
agrestis, Lolium temulentum, and Agropyrum repens, of which H. vulgare and
F. elatior are said to be new hosts for this fungus.

Sphacelotisca reiliana on Sorghum halepense, O. Munerati (Staz. Sper.
Agr. Ital., 43 (1910), No. 10, pp. 718-722, figs. 2).—Attention is called to the
occurrence in Italy of this smut on Johnson grass.

Rhizoctonia of buckwheat, F. L. Stevens and G. W. Wilson (Abs. in Science,
n. ser., 33 (1911), No. 859, p. 943).—At the tenth annual meeting at Raleigh
of the North Carolina Academy of Science mention was made of the serious outbreak of Rhizoctonia on buckwheat in the western part of the State.

Notes on the value of treating the seeds of winter cereals with corrosive sublimate, L. Hiltner (Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 9 (1911), No. 5, pp. 69-79, fig. 1).—After a brief discussion of the value of soaking the seeds of wheat and rye in a corrosive sublimate solution as a means of protection against Fusarium and other fungi, the spores of which cling to the surface of the grains, the author gives reports obtained from many grain growers on the effects of the formalin treatment of the seed and on the germination and vigor of growth.

It is claimed that no injuries resulted to the grain from the corrosive sublimate treatment, and that better germination and more vigorous growth were obtained.

The action of some fungicides on the germination of certain varieties of wheat and oats, G. D'Ippolito (Staz. Sper. Agr. Ital., 53 (1910), No. 10, pp. 735-757).—The effects on the germinative power and length of germination when the seeds of various varieties of wheat and oats were treated with sulphate of copper and milk of lime are given.

It was found that a 0.5 per cent solution of copper sulphate lowered more or less the degree of germination and the germinative energy on all the varieties tested except 2 of wheat, while a seed treatment with a 0.25 per cent solution of copper sulphate did not injure the germinative power of the grain, nor did it increase the period of germination. A 5 per cent solution of milk of lime did not injure the germination of the treated grain in any way, but on the contrary was beneficial to it except in the case of 2 varieties of oats.

A bibliography is appended.

Bean diseases, S. B. McCready (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 36 (1910), pp. 44-47, figs. 2).—The author describes 3 common and serious bean diseases, viz. anthracnose (Colletotrichum lindemuthianum), bacterial blight (Pseudomonas phascoli), and pod and stem rot (Rhizoctonia), and gives methods for their control.

Results of a practical attempt to control lettuce sclerotiniose, F. L. Stevens (Abs. in Science, n. ser., 33 (1911), No. 859, p. 941).—At the tenth annual meeting at Raleigh of the North Carolina Academy of Science the author reported the results of experiments on the control of lettuce sclerotiniose. From the studies made it was decided that all the fungus structures except the sclerotia are short-lived, and, therefore, that if the formation of new sclerotia could be prevented, diseased beds could be eventually restored to health.

To test this, several experimental beds were thoroughly infected in 1908, and the sclerotia which formed were allowed to remain in the beds. The following year over 45 per cent of the lettuce died with sclerotiniose. From this time on a course of treatment designed to prevent the formation of sclerotia was followed, with the hope of lessening the disease. The following year only 1 of 1 per cent of the crop died. A year later (1911) the results were almost the same.

Tomato blight and rot in Virginia, H. S. Reed (Virginia Sta. Bul. 192, pp. 16, figs. 9).—After a general discussion of the characteristics of these 2 diseases and of their serious menace to tomato growing in southern Virginia, the author gives the results of spraying and fertilizer experiments conducted during 1910 at Christiansburg and Blacksburg on the control of these diseases.

The experiments consisted of from 2 to 4 applications of 4:5:50 Bordeaux mixture, 1:33 and 1:50 commercial lime sulphur, and of applications to the soil around the plants of sulphur (a handful to each plant), sulphate of
potash (300 lbs. per acre), acid phosphate (300 lbs. per acre), lime (1 ton per acre), and stable manure (15 tons per acre).

From 3 to 4 applications of the 4:5:50 Bordeaux mixture proved uniformly successful in controlling both the tomato blight (Septoria lycopersici) and rot (Phytophthora sp.). The 1:33 and 1:50 lime-sulphur sprays acted variably, giving good results in 1909, but they were not nearly so efficient in 1910 in controlling these 2 diseases as the Bordeaux mixture. The various sprays were applied July 11 to 12, August 1 to 2, August 15 to 18, and September 2. The treatments with sulphur, manure, or fertilizers had no effect in controlling these diseases.

Parasitism of Coniothyrium fuckelii, P. J. O’Gara (Phytopathology, 1 (1911), No. 3, pp. 100-102, pls. 3).—The author reports the results of successful inoculation and cross-inoculation experiments with this organism on both apples and roses.

The disease was first observed in 1903 on apple twigs and young apple trees from South Carolina. These specimens showed cankers of various sizes, the surface of which bore numerous minute pycnidia. Young apple trees were infected just above the crown, and in the earlier stages of the disease the bark tissues still adhered to the wood, but in the older infections the dead bark broke away. About the same time specimens of diseased rose stems affected with canker were found at Washington, D. C., which on examination proved to be very similar to the apple canker. Subsequent growth in pure cultures and cross inoculations from both hosts to apple and rose proved the identity of the 2 organisms.

This organism also causes a fruit rot of the apple, in which circular, brownish, and somewhat sunken areas are produced. The diseased area is smooth at first, and later becomes somewhat wrinkled, while the mycelium in the earlier stages is densely white, and later becomes brown. The apples are often completely rotted when attacked by the disease. In South Carolina most of the infection occurred where the bark had been injured by tools and cultivating. Nursery stock adjoining a clump of wild roses badly attacked by the disease was seriously infected.

A dangerous apple disease, F. L. Stevens and G. W. Wilson (Abs. in Science, u. ser., 33 (1911), No. 859, p. 912).—In a paper read before the tenth annual meeting, at Raleigh, of the North Carolina Academy of Science, attention is called to a serious apple disease which appeared in 1908.

The disease is characterized by whitish or pinkish pustules on the younger twigs and about the crotches of the tree, from which numerous spores of the Fusarium or Tubercularia type develop. The infection is in the bark, the diseased areas shrinking and separating. The epidermis splits away, exposing the brown surface beneath, or the pustules merely break through the epidermis, especially near the lenticels. Upon older twigs the bark cracks longitudinally, exposing rows of pustules in the cracks. A pinkish mycelial growth sometimes appears on the diseased twigs. No ascigerous stage has been found.

The orchard on which the test was made had never been sprayed and was badly infested with these diseases. Three sprayings were given, viz, the first with home-boiled lime sulphur just before the leaves opened, the second with a 1:30 commercial lime-sulphur solution applied as the blossom buds were opening, and the third with a 1:30 commercial lime sulphur when the blossoms were falling. Arsenate of lead was used as the insecticide.
At harvest time it was found that 90 per cent of the apples were free from scab, and very few showed any signs of black rot, while other nearby unsprayed orchards were badly attacked by the scab.

A preliminary report on the effects of arsenical compounds upon apple trees, D. B. Swingle and H. E. Morris (Phytopathology, 1 (1911), No. 3, pp. 79–83, pls. 2).—The results are given of experiments made in an orchard which had never been sprayed with any arsenical, in which the effects on the bark of fruit trees of the common insecticides were tested. Tests were also made as to which compounds are the most injurious, and the nature and extent of the injuries.

The following compounds were applied: Arsenic acid (pure), arsenic trioxid (highest purity), arsenic disulphid, arsenic trisulphid (technical), calcium arsenite, lead arsenate (technical), Paris green, sodium arsenite (pure), and zinc arsenite. The chemicals were applied to branches from ¼ to 2½ in. in diameter, on bands of absorbent cotton which were wrapped about the limbs in such a manner that the chemicals made a uniform layer of about 4 in. wide, and were kept wet with distilled water. Crowns from 3 to 5 in. in diameter were also treated, by digging a shallow trench close around the tree, partly filling it with the chemical suspended in water, and replacing the earth. Tabulated data are given showing the kind of arsenical used, the amount of the arsenical by weight, the variety of tree treated, the diameter of the treated portion, wounds under the bandage holding the chemicals, and the extent and character of injury. Investigations were also made as to the number of cells in the corky layer of smooth bark and in the furrows of rough bark.

It was found that serious injury to apple trees may result under certain conditions from the application of so-called insoluble arsenicals, and that recent wounds through the outer bark, functional lenticels, and dormant buds permit the absorption of arsenicals in solution, recent wounds being especially dangerous. The cutting off of water sprouts from the bases of trees in early spring and the subsequent accumulation of arsenicals used as insecticides about the unprotected wounds were found to be dangerous. White-lead paint applied to these wounds will protect against arsenical injury, even when the paint is put on just before the spraying.

The most noticeable symptoms of rapid arsenical injury through the bark are a discoloration of bark and outer wood along definite lines up and down the stem and a dull spotting of the leaves, followed by wilting, shriveling, and drying. The injury seems to be due more to the soluble impurities in the arsenicals than to the slight solubility of the compounds themselves. Arsenic trisulphid when applied to the bodies of trees did not seem to be more safe than the other arsenicals in common use, but zinc arsenite gave practically no injuries under the most severe tests.

Researches on the diseases of the grape, J. Capus (Bull. Mens. Off. Renseig. Agr. [Paris], 10 (1911), No. 4, pp. 456–464).—Two lines of study are reported, one on the spread of the black rot and mildew in 1909, and the other on the comparative efficacy of different copper sprays as determined by the length of action of each on the vines.

It is stated that 2 sets of conditions govern the ease with which these diseases attack the grape, as follows. The first set includes diminished daily growth of the branches, the disappearance of starch from the upper internodes, and the cessation of growth of the rootlets, accompanied by heavy rains which wet the earth and by a lowering of the temperature. The second set includes the atmospheric conditions such as sufficient warmth and moisture for the germination of the spores. When these 2 sets of conditions coincide the infection will be certain and rapid, and the intensity of each attack under these favorable
conditions will be determined by the number of spores which exist in the neighborhood of the vines.

As to the various sprays tested, the author lists the following in order of efficiency: (1) Bordeaux and Burgundy mixtures (3 to 4 parts to 100 of copper sulphate); (2) Burgundy (2:100), Bordeaux (2:100), Burgundy (2:100 with collophony), Bordeaux mixture plus molasses, Burgundy (2:100 plus soap), and copper acetate (1:100 and 2:100); (3) Burgundy and Bordeaux mixtures (2:100, applied 4 and 8 days after mixing); (4) Bordeaux and Burgundy mixtures (1:100); (5) oxychlorid of copper (500 gm. per hectoliter); (6) oxychlorid of copper (300 gm. per hectoliter), ammoniate of copper (1:100 and 2:100); (7) chlorid of copper (240 gm. per hectoliter); and (8) aceto-arsenite of copper (200 gm. per hectoliter), and sulphate of copper (150 to 500 gm. per hectoliter).

Spraying for black rot of the grape in a dry season, D. Reddick, C. S. Wilson and C. T. Gregory (New York Cornell Sta. Bul. 296, pp. 573–588, figs. 4).—The results are given of experiments conducted during 1909 and 1910 on spraying with ammoniacal copper carbonate, Bordeaux, and lime-sulphur mixtures for the control of the black rot of the grape, in continuation of previous work (E. S. R., 21, p. 344).

The experimental plats were located in a vineyard from which no grapes had been picked for many years because of the ravages of the black rot and downy mildew. The sprays used during 1909 were 4:4:50 Bordeaux mixture (4 and 5 applications), 3:3:50 Bordeaux mixture (5 applications), 10:6:50 ammoniacal copper carbonate (5 applications), 1:25, 1:30, and 1:40 commercial lime-sulphur mixture (5 applications), and 8:8:50 self-boiled lime-sulphur mixture (5 applications). Some tests were also made with bagging the fruit as a means of controlling the disease.

In 1910 the sprays used were 4:4:50 Bordeaux mixture (2, 3, and 4 applications), 1:50 and 1:65 commercial lime-sulphur mixture (4 applications), 8:8:50 self-boiled lime-sulphur mixture (4 applications), and 5:3:50 ammoniacal copper carbonate (4 applications).

The results from these experiments for the 2 seasons showed that with the best fungicide used for controlling the black rot the applications necessary to control the disease were applied with actual loss when compared to the yields during these 2 years from the unsprayed vines. All of the sprays used were ineffective against the rot except the 4:4:50 Bordeaux mixture, which maintained its preéminence as a spray for black rot. The time of application of the sprays proved to be the most important single factor in the control of this disease.

The author recommends clean culture of the vineyard grounds, the destruction of all mummies left on the vines, keeping the vines clear of basal trailing sprouts, and spraying with a 4:4:50 Bordeaux mixture, the first application of the mixture being made when the third leaf is showing, the second just after the fall of the blossoms, and two other applications at intervals of 10 to 14 days, according to the weather conditions. Each application should precede rather than follow a rain, as it was found that an infection followed only a rain of some duration.

The conditions of resistance of the vines to mildew, J. Laurent (Bull. Mens. Off. Renseign. Agr. [Paris], 10 (1911), No. 4, pp. 464–471).—The substance of this article has previously been noted from other sources (E. S. R., 25, p. 45).

Scaly bark or nail-head rust of citrus, H. S. Fawcett (Florida Sta. Bul. 106, pp. 1–41, figs. 22).—This bulletin comprises the results of several years' study of this disease, in which the cause of scaly bark, means of control, symptoms, distribution, history, and development were investigated; inoculation experiments and experiments for the control of the disease are also given. The
cause of the disease, methods of control, and inoculation experiments have been
previously noted from other sources (E. S. R., 23, p. 416; 25, p. 450).

The disease has been known on the Pinellas Peninsula, Florida, for at least
30 to 40 years, but has done little damage until recently. It is caused primarily
by Cladosporium herbarum citricolum, but is associated with the withertip
fungus (Colletotrichum gloeosporioides), which is an important secondary agent
in the destruction wrought by the disease. The cultural characteristics of
C. herbarum citricolum on various media and in comparison with C. herbarum
are given. Inoculation experiments with pure cultures of the fungus on young
orange trees in the greenhouse and on unripe oranges in the laboratory resulted
in the formation of spots similar to scaly bark spots.

From the experiments conducted on the control of this disease the following
conclusions are drawn: (1) The disease yields to spraying with Bordeaux mix-
ture; (2) pruning out of the dead wood lessens subsequent infection; (3) car-
bolineum, one-half strength, painted over the bark after heading back, is fol-
lowed by a vigorous growth free from the disease; (4) neither spraying with 1
per cent solution of carbolineum nor spreading copper sulphate in the form of
crystals on the ground was found to be of any practical value in controlling
the disease.

In conclusion, it is stated that scaly bark is a disease of the fruit and bark,
mainly of the sweet orange, and occurs in only a few localities in Florida. In
addition to the other remedies for controlling this disease, it was found that
budding or grafting to resistant varieties of citrus, such as pomelo, mandarin,
and tangerine (Citrus nobilis) was effective.

A bibliography is appended.

The double blossom of the dewberry (Fusarium rubi), M. T. Cook (Del-
aware Sta. Bul. 93, pp. 3-12, figs. 12).—In addition to a discussion of the dis-
tribution and characteristics of this disease, to which attention had been previ-
ously called by the author (E. S. R., 23, p. 453), a study is reported of the
penetration of the fungus into the tissues of the host. spore distribution, method
and time of infection, damage done by the fungus, and of methods for its
control.

It was found that the mycelium of the fungus (F. rubi) did not penetrate the
tissues, but grew between the various elements of the leaf bud. Later, however,
the flower buds are penetrated by the mycelium, and the hyphae enter the
ovaries by way of the stigma and style and form a mass of mycelia in the ovary
cavity. Conidia are produced within 48 hours after the opening of the flower
buds. These spores fall on the young buds which are forming for the next
year, germinate, and grow inward, where the mycelium remains dormant until
the following spring. The disease is said to be more severe on the Lucretia and
Rathbone varieties of the dewberry, but attacks many species and varieties of
the genus Rubus. It is claimed that as the mycelium does not penetrate beyond
the base of the buds, the hand-picking of the diseased buds, which are easily
recognized by their somewhat more swollen and reddish appearance in the early
spring, should prove an effective means of control. Experiments comparing
hand-picking and spraying showed that hand-picking kept the disease in check
though not eradicating it completely, while spraying proved ineffective in com-
bating it.

Is Bacillus coli ever a plant parasite? J. R. Johnston (Phytopathology, 1
(1911), No. 3, pp. 97-99).—The results of inoculation experiments with this
organism on the coconut are reported, as well as inoculation and cultural
studies of certain organisms isolated from the bud rot of the coconut palm.

As a result of these inoculations and the subsequent cultural studies, the
conclusion is drawn that at least one organism capable of causing the bud
rot of the coconut palm has been identified, and after a careful study of the
organism and comparison with \( B. \) coli it was found impossible to ascertain
any characters by which the coconut organism could be distinguished from
the \( B. \) coli received from the animal pathological laboratory.

It is concluded, therefore, that either \( B. \) coli or a form indistinguishable from
it by our present method of research is the cause of the coconut bud rot.

Misc. Inform., 1911, No. 1, pp. 60–62).—The author reports a study of the
mode of entrance and the range of hosts of a fungus (\( D. \) pinea) found in the
diseased shoots of \( Pinus \) insignis and \( P. \) montana from Cape Colony.

The disease is confined to the terminal portions of the shoots, and is char-
acterized by the yellowing and subsequent shedding of the leaves, followed by
the death of from 10 to 18 in. of the terminal portion of the shoots. These
dead shoots remain attached to the tree, and furnish successive crops of
spores

Inoculation experiments with the spores of this fungus on unbroken surfaces
of the host gave negative results, but when drops of water containing spores
were placed on wounded surfaces infection occurred. In the experiments re-
ported species of \( Pinus \) were readily infected through wounds, but not \( Picea,
Abies, \) or \( Larix. \)

The rusts of Tsuga canadensis, P. Spaulding (Phytopathology, 1 (1911), No.
3, pp. 94–96, figs. 2).—The author reports the occurrence and range of \( Perider-
mium \) peckii and \( P. \) fructignum, of which \( Cwoma \) tsuga is a synonym. The
latter occurs in 2 forms, one on the scales of the green cones and the other
on the young newly formed shoots of \( T. \) canadensis.

Fungus diseases; their relation to Para rubber cultivation in the West
Indies, K. Bancroft (West India Col. Circ., 26 (1911), Nos. 329, pp. 220–223;
330, pp. 255–257; 331, pp. 268–270).—The author gives the characteristics of
the following diseases, and suggests methods of control for several of them:
Root diseases caused by \( Fomes \) semitostus, \( Hyphaenechate \) naria, and \( Spharos-
tilic \) repens; stem diseases caused by \( Corticium \) javanicum, \( Thyridaria \) tarda
(Diplodia caecaolea), \( Phytophthora \) faber, thread blight fungus, die back
(\( Gloeosporium \) alborebrum and Diplodia), and \( Etypo \) canticora; leaf diseases
caused by \( Pestalozia \) queqini, \( P. \) palmarum, and several minor fungi; and a
fruit disease due to \( Phytophthora \) faber.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Progress of game protection in 1910, T. S. Palmer and H. Oldys (U. S.
Dept. Agr., Bur. Biol. Survey Circ. 80, pp. 36, fig. 1).—In this annual report
on the subject (E. S. R., 23, p. 253), it is shown that the year 1910 was marked
by steady progress in the movement for the increase of game by propagation
and the establishment of game preserves. A chronological record of events
relating to game protection during the year is appended.

233–254, maps 6).—In this paper the author discusses the early abundance of
game, the increase in prices of game, present condition of game, causes of de-
crease, restrictive laws, markets, and the present market supply.

Killing ground squirrels, W. D. Foster (Washington Sta. Popular Bul. 35,
pp. 4).—As the result of serious injury to corn on the college farm in 1904
considerable poison was used during the remainder of the year, but apparently
without much effect.
In March, 1905, 200 steel traps were set, uncovered and unbaited, each trap being visited at least twice daily. Poison was also used to a moderate extent. A total of 925 squirrels was killed, at an estimated cost of $92. In 1906 the same methods and more traps were employed and 1,656 squirrels killed, at a cost of $112. In 1907, 170 acres were added to the college farm, making a total of over 400 acres, 1,875 squirrels being killed, at a cost of $170. The work was continued through to 1910, 1,764 squirrels being killed in 1908, 1,280 in 1909, and 460 in 1910, the cost being $172, $140, and $82, respectively.

The average cost of killing squirrels for the entire period was a little less than 9 cts. each, exclusive of the cost of the traps. It was found that, aside from the necessary protection to the experimental plats and crops, the squirrels were destroyed at a cost much below the damage which they would have caused if allowed to remain. As an argument in favor of trapping rather than poisoning, the author cites a case in which 60 horned larks were killed on a 5-acre field by poison intended for squirrels.

Rats and fleas in their relation to bubonic plague, A. H. Jennings (Proc. Canal Zone Med. Assoc., 1910, Apr.–Sept., pp. 119–133).—The author here reports upon investigations made of the species of rats and fleas and their distribution in the city of Panama and the Canal Zone.

The rats trapped in the routine work of the Panama Department of Health were delivered to the Board of Health Laboratory, where they were chloroformed and searched for fleas. In all, 2,292 rats of four species were examined. They were brown rats, 1,513; black, 653; roof, 77; mouse, 49. From these rats 2,784 fleas were taken. Single rats often greatly exceeded the average of their species, the highest number for one rat being 39 fleas. But two species of fleas were taken from the rats examined, the Indian rat flea, Xenopsylla cheopis, and the cat flea, Ctenocephalus felis, the former forming 97.9 per cent of the entire number. Three other species of fleas, namely, the European rat flea, Ceratophyllus fasciatus; the European mouse flea, Xenopsylla musculi; and the human flea, Pulex irritans, have, however, been taken from or are thought to occur in the Canal Zone.

A tabulated summary is given of the relationship of rats and fleas taken from districts in the city of Panama.

The migratory movements of birds in relation to the weather, W. W. Cooke (U. S. Dept. Agr. Yearbook 1910, pp. 379–399, map 1).—The data here presented are based on 400,000 records.

It is shown that “weather conditions are not the cause of the migration of birds, but that the weather, by influencing the food supply, is the chief factor which determines the average date of arrival at the breeding grounds. Migration is undertaken in response to physiological changes in birds, and the date of starting in the case of most species bears no relation whatever to the local weather conditions in the winter home. The weather encountered en route influences migration in a subordinate way, retarding or accelerating the birds’ advance by only a few days and having a slight relation to the date of arrival at the nesting site. Local weather conditions on the day of arrival at any given locality are minor factors in determining the appearance of a species at that place and time. The major factors in the problem are the weather conditions far to the southward, where the night’s flight began, and the relation which that place and time bear to the average position of the bird under normal weather conditions . . .

“Another conclusion equally apparent is that neither the time of migration, the route, nor the speed of one species can be deduced from records of other species, even though closely related; in other words, each species and even each group of individuals of a species is a law unto itself.”
Common Michigan birds, W. B. Barrows (East Lansing, Mich., 1911, pp. 35, figs. 8).—A brief popular account.

Flowers and insects, their adaptation to one another and their mutual dependence, O. von Kittner (Blumen und Insekten Ihrer Anpassungen Aneinander und Ihre gegenseitige Abhängigkeit. Leipzig and Berlin, 1911, pp. IV+436, pls. 2, figs. 159; rev. in Science, n. scr., 34 (1911), No. 863, pp. 57, 58).—This work consists of 16 chapters and an index.

Following the introduction, 2 chapters are given up to a discussion of pollination, the various ways in which it is brought about, and the peculiarities of insect pollination, or entomogamy. A chapter on the insects that visit flowers and their structural adaptations is followed by one on the general adaptation of flowers to insects. Chapters 6 to 13 are devoted to a discussion of the structure of flowers and the various types of entomogamy while the 3 concluding chapters deal with floral statistics, the causes of mutualistic adaptations of flowers and insects, and the various hypotheses which have been advanced to account for the phylogenetic origin and development of floral structures.

The review is by W. M. Wheeler.

Insect notes for 1910, O. A. Johanssen (Maine Sta. Bul. 157, pp. 24, pls. 8).—This is a report of observations on the occurrence of and injury caused by insects in Maine during 1910.

Among the more important insects thus noted are the fall webworm, the saddled prominent (Heterocampa guttivitta), the birch leaf Bucculatrix (Bucculatrix canadensisella) as a leaf miner, parthenogenesis and pedogenesis in Tanytarsus dissimilis, the carrot rust fly (Psila rosea) on parsnips, the fringed anthomyia (Phorida fusciceps), Phormia regina, Amplicoma vulpina, the alder borer (Superda obliqua) infesting birch, the black vine weevil (Otiokrhynchus sulcatus), Aulac glechoma, Tormyns flavicora, Eurytoma gigantea, the chinch bug, European elm scale, and several other scale insects.

Notes presented by Edith M. Patch on the Psyllideae and Aphididae include descriptions of 4 new species of the former, viz., Psylla galeformis taken from the leaves of the alder (Alnus incana), P. striata from the tips of birch shoots, Aphalara veaziei swept from golden rod, sweet fern, grass, etc., and Triozia obtusa bred from nymphs developing on Amelanchier canadensis. Notes are also presented on Mindarus abietinus, the occurrence of Cermes cooleyi in New York, etc.

Cutworms, army worms, and grasshoppers, F. L. Washburn (Minnesota Sta. Bul. 123, pp. 67-84, pl. 1, figs. 12, map 1).—Briefly illustrated accounts are given of cutworms, army worms, and grasshoppers, and of preventive and remedial measures therefor.

Insect enemies of tobacco in the United States, A. C. Morgan (U. S. Dept. Agr. Yearbook 1910, pp. 281-296, pl. 1, figs. 13).—The article here presented, summarizing the data on insect enemies of tobacco and remedies, is in a measure supplementary to that by Dr. L. O. Howard on tobacco insects, previously noted (E. S. R., 11, p. 471).

Under the heading of insects of primary importance, the author considers the tobacco flea beetle, Epitrix parvula; cutworms; the tobacco hornworms, a more extensive account of which has been previously noted (E. S. R., 23, p. 465); the budworms, Chloridea virescens and Heliolithis obsoleta; the tobacco splitworm, Phthorimma operculella; the tobacco thrips, Euthrips fuscus (nicotianae); the tobacco crambus, Cranitis caliginosellus (?); and the cigarette beetle, Lasioderma serricorne.

The insects of secondary importance are discussed under the headings of insects attacking the seed bed, young transplanted plants, the foliage, the stem, the root and stem, cured and manufactured tobaccos, and tobacco seed, respectively.
Some insects and mites attacking the peach in Colorado, G. P. Weldon (Colorado Sta. Bul. 169, pp. 3-13, pl. 1, figs. 2).—The peach-twig borer (Anarsia lineatella) has been known in Colorado for a number of years, and while not a seriously injurious pest every season, there are seasons when it becomes exceedingly destructive and is responsible for a great financial loss to those peach growers who do not adopt proper methods of control.

The larvae hibernate in little silk-lined chambers constructed within the bark and very close to its surface. They have been found by the author in Colorado almost entirely in the older crotches, and always, when found there, they have been in the brown portion of the bark just as close to its surface as the hibernacula could be constructed. Occasionally the hibernating cells containing larvae have been found underneath buds on the new growth of peach trees, but their occurrence in this location does not seem to be at all general. The presence of the larvae during the hibernating period can be detected by the tiny silken tubes, covered on the outside with bits of bark, which they construct at the entrance to their burrows. Frequent reference is made by the author to the bulletins on this insect by Mariott, of the Bureau of Entomology of this Department (E. S. R., 10, p. 569), and by Clarke, of the California Station (E. S. R., 14, p. 590).

Although there was a scarcity of the twig borer in 1910, experiments conducted show that "Rex" lime and sulphur gave perfect results. "One tree sprayed with black leaf, 1:70, was free from wilted tips, and also 2 trees sprayed with black leaf '40,' 1:600. . . . Black leaf '40,' 1:600, apparently gave good results. . . . For some unknown reason, home-prepared lime and sulphur used at the same time as the 'Rex' spray, but in another orchard, apparently did little good." However, from experiments conducted in 1910 at Clifton, from the experience of many Colorado orchardists who have used lime and sulphur for the control of this pest, and from the apparent success of this spray in California, the author feels justified in recommending its use in sections of Colorado where there is injury from the twig borer.

"While arsenate of lead was a total disappointment in this season's test, it has previously been used with good success and is no doubt effective when applied at the proper time."

The other insects briefly noted are the San José and Putnam scales, the peach-borer, the brown mite (Bryobia pratensis), and red spider (Tetranychus bimaculatus), previously noted (E. S. R., 23, p. 264).

Two plant lice of the peach, C. P. Gillette and G. P. Weldon (Colorado Sta. Bul. 169, pp. 13-20, fig. 1).—Accounts of the green peach aphis (Myzus persicae) and the black peach aphis (Aphis persicae-niger) by the senior author have been previously noted (E. S. R., 20, p. 854).

The hibernation and spring, summer, and fall habits of the green peach aphis here described are followed by accounts of spraying experiments, the conclusions drawn from which are as follows: "Lime and sulphur, both 'Rex' and home-prepared, black leaf extract, black leaf '40,' and soluble oil, may be effectively used for the control of the green peach aphis when applied in the early spring, just as the eggs are hatching. A lime and sulphur spray is not effective when applied 2 weeks or more after the eggs are hatched, for at this time the stem-mothers are mature, or nearly so, and are able to resist the action of this insecticide. Good tobacco preparations may be used with success any time after the aphids hatch; but it is more difficult to succeed late in the spring, because it is then more difficult to get the spray on all the lice, on account of the protection of the leaves. The best time to spray for this insect is in the early spring when the eggs are hatching."
As yet the black peach aphis has not been of much economic importance in Colorado, although found from time to time in the peach-growing sections of the Western Slope.

Aphidiinae of North America, A. B. Gahan (Maryland Sta. Bul. 152, pp. 176-200, figs. 11).—This is a synopsis of the braconid subfamily Aphidiinae, the species of which are parasites of plant lice. Ten genera are recognized as belonging to the subfamily of which those that occur in North America are represented as follows: Ephedrus, by 4 species; Monoctonus, 1 species; Prnaon, 9 species; Aphidius, 23 species; Lysiphlebus, 3 species; Discretus, 4 species; and Trioxys, 3 species.

"The study of the types has been supplemented wherever possible by study of cotype and homotype material, as well as of large series of reared specimens of various species and some breeding work from known parents. The genera and species placed in synonymy have been so treated only after careful consideration and in the light of the knowledge gained of the range of variation from the study of extensive series of reared specimens from numerous hosts. Five new species are described, and in order to point out new characters, correct errors in former descriptions, obviate the confusion in certain cases resulting from the numerous descriptions of the same species under different names, as well as to bring the decriptions all together in a convenient form for reference, a redescription is included of all the established species of which authentic specimens could be obtained."

The species described as new, are Ephedrus nigricornis from Fort Collins, Colo., host unknown; Aphidius gillettii, reared from Lachnus sp. on Abies lasiocarpa at Fort Collins, Colo.; A. juniperaphidis, parasitic on Lachnus sp. on Juniperus sibiricus, at Boulder, Colo.; Lysiphlebus flavidus, parasitic on Aphis albipes at Fort Collins, Colo.; and Trioxys conescuiclagus, parasitic on Macrosiphum frigida at Fort Collins, Colo. Tables for the separation of the genera and species are included.

Catalogue of the Lepidoptera Phalænae in the British Museum.—X, Catalogue of the Noctuidæ in the collection of the British Museum, G. F. Hampson (London, 1910, vol. 10, pp. XIX+829, figs. 211; 1911, vol. 10, pls. 26; rev. in Nature [London], 85 (1911), No. 2156, p. 539).—This volume is devoted to the Erastriæ, the thirteenth of the subfamilies of the Noctuidæ recognized by the author. It contains descriptions of 1,222 species belonging to 136 genera, a considerable number both of the genera and species being described as new.

The fauna of British India, including Ceylon and Burma, edited by A. E. Shipley and G. A. K. Marshall (London, Calcutta, and Berlin, 1910, vol. 5, pp. XII+362, figs. 214; rev. in Nature [London], 86 (1911), No. 2165, p. 277).—In this supplementary volume, extending from the family Lygæidae to the family Corixidae, the author describes a large number of species, completing his work on the Indian Heteroptera. It is announced that a further volume is to be issued, which will form an appendix to the Homoptera, will complete the enumeration of the Indian Rhynchota, with the exception of the families Psyllidae, Aphidiidae, Aleurodidae, and Cocidae.

The wheat-head army-worm as a timothy pest (Meliana albilinea), R. L. Webster (Jouva Sta. Bul. 122, popular ed., pp. 3-7, figs. 5).—This is a popular edition of Bulletin 122, previously noted (E. S. R., 25, p. 55).

Sugar cane borers in British Guiana, J. J. Quelch (Abs. in Agr. News [Barbados], 10 (1911), No. 236, p. 154).—The giant moth borer (Cactnia bicus) and the smaller moth borer (Diatraca saccharalis) and their control are discussed in this interim report.

The fresh water fauna of Germany, K. Grünberg (Die Süßwasserfauna Deutschlands. Jena, 1910, vol. 2 A, pt. 1, pp. IV+312, figs. 348; rev. in Science,
EXPERIMENT STATION RECORD.

n. scr., 33 (1911), No. 851, p. 623).—The first part of this volume takes up the Diptera that have aquatic larvae, with the exception of the Chironomidae, which will be treated in the second part. Synoptic tables to the genera and species and in many cases to the genera of the larvae as far as known are included. Many of the genera and a number of the species taken up occur in this country.

Injuries to forests and forest products by roundheaded borers, J. L. Webb (U. S. Dept. Agr. Yearbook 1910, pp. 331-358, pl. 1, figs. 11).—In this paper the author treats briefly of 11 species of roundheaded borers.

"The western larch bark-borer, Tetropliun velutinum, attacks perfectly healthy western larches, making winding, irregular galleries in the inner bark, thus cutting off the flow of sap and killing the trees. The methods of control are preventive. No attempt is made to save a tree which has once become badly infested. After becoming infested, trees should be felled and barked and the bark burned before the following May 15. A few healthy trees felled in May or June, near those infested, should attract the beetles which would otherwise deposit eggs in healthy trees. Before the following spring the bark should be stripped from these trap trees and burned."

The southern pine sawyer, Monachaumus hilisator, which is very destructive to felled pine timber in the Southern States has previously been considered (E. S. R., p. 260). An account of the locust borer, Cyllene robinia, has also previously been noted from another source (E. S. R., 18, p. 158).

"The painted hickory borer, C. carica, attacks dead and dying hickory, walnut, honey locust, mulberry, and Osage orange, the larval mines often riddling the sapwood and sometimes the heartwood as well. To prevent the spread of this species, all cutting of green timber should be done between August 10 and November 1. Timber which must be cut in spring or early summer should have the bark removed and the tops and useless branches burned.

"The black-horned pine-borer, Calilium antennatum, is an enemy of dead or dying cedar, juniper, pine, and spruce. Rustic work is especially liable to injury from this source. As a preventive against injuries by this species, cedar, juniper, pine, and spruce should be cut in late summer, fall, or early winter. If cut between January and August the trees should be barked when felled. In the case of injuries to rustic work, an injection of bisulphid of carbon and the plugging up of the holes with wax or putty is recommended.

"The cedar-tree borer, Hylotrupes lignuens, attacks dead and injured Douglas fir, arbor vitae, red cedar, redwood, western hemlock, Engelmann spruce, juniper, alpine fir, giant arbor vitae, white fir, big tree, and Arizona cypress. Like the black-horned pine-borer, it is injurious to rustic work. The usual preventive measures are recommended, i. e., removing the bark from trees when felled, or treating rustic work as recommended for the black-horned pine-borer."

The western cedar bark-borer, H. amethystinus, which has been found only in the Pacific Coast States, is of considerable economic importance in injuring the bark and wood of recently felled giant arbor vitae and incense cedar. There is thought to be but one generation of this beetle per year and that adults emerge and deposit eggs in July, August, and September. The same recommendations for preventing injury as those given for the cedar-tree borer are applicable to this species.

The banded ash borer, Necolytus caprae, is apparently the most destructive borer affecting ash, the larvae perforating the sapwood with their mines and greatly depreciating its value, if not entirely ruining it. Besides ash, the borer attacks and lives in mesquite and, rarely, in white oak. The removal of the
bark immediately upon felling or between March 1 and June 1 and the placing of the logs in water after the larvae have hatched and before they have entered the wood are recommended as preventives.

The red-headed clytus, *Neoclytus crythrocephalus*, does considerable damage to the wood of dead and dying ash, as well as to a number of other trees. Its host plants include the hornbeam, hickory, maple, sweet gum, chestnut, cypress,hackberry, black walnut, dogwood, black oak, persimmon, peach, locust, sassafras, holly, mesquite, Texas redbud, pine, Kentucky coffee tree, lilac, honey-suckle, and grapevine. "The same preventive measures as those given for the banded ash borer apply to this species except, it will be noted, that the egg-laying period of this species is much longer than that of the banded ash borer, so that there is scarcely any season of the year when trees may be cut and left with bark on without danger of being damaged by this borer."

The work of the oak pruner, *Elaphidion villosum*, and the hickory twig-girdler, *Oncideres cingulata*, which is confined to the twigs and branches, is often quite injurious. When these species occur in injurious numbers, the fallen twigs and recently killed twigs of the trees should be gathered and burned in the fall in order to destroy the larvae and pupae in them. For the hickory twig girdler this should be repeated before vegetation starts in the spring and again during June or July.

The twig girdler (*Oncideres cingulata* and *texana*), C. E. Sandborn (Oklahoma Sta. Bul. 91, pp. 13, figs. 7).—The twig girdler, which is known to occur throughout the United States east and south of and including Kansas, subsists during its larval period on the wood of branches which have been girdled from the tree by the adult female. The adults begin to emerge about the first of August from branches girdled the previous fall. Within one or two weeks after emergence the sexes pair, and the females begin to girdle and generally, after completing the girdle, commence to oviposit in that part girdled from the tree. In rare instances, however, they oviposit at intervals in the branch while the process of girdling is under way. The branch is girdled entirely around or until it has become so weakened that it bends downward. "One female can easily girdle all of the branches from 2 5-year-old trees or 5 3-year-old trees, or 15 or 20 2-year-old trees. The direct damage, therefore, caused by the girdling of select stock can easily be computed at about $10 per female beetle without taking into consideration the damage caused by the pernicious food habits of both sexes."

In Oklahoma oviposition commences about the first of September and continues until the time of heavy frosts late in the fall. "The number of eggs deposited by a single female varies from about 10 to 150. The greatest number I have found in a single girdled branch is 30. . . . The larvae do not all hatch until late in winter. The egg generally hatches within about one week after it is deposited. The larva emerges from it at the end nearest the puncture, between which points there is a vacant space in which it first feeds by eating the soft tissue bordering the hard wood. As development proceeds it eats the hard wood cells in proximity to the water tubes leading from the leaf scars near the base of the bud or twig." Technical descriptions of the different stages accompany the account.

The author's observations prove conclusively that there is but one generation per year, the season of adult activity being from August until frost. Experiments conducted show that decaying wood is not suitable for the development of the larvae, as previously supposed. They prove that the best conditions for the hatching of the eggs and the development of the larvae is in twigs which do not fall to the ground but hang on the branches or trunk of the tree, thus protected from the soil moisture and natural enemies of the developing beetles.
The next best conditions are where the branches may fall on hard ground where they may be protected from moisture to some extent and consequent decay.

During the season of oviposition the females should be captured by hand in the infested orchards. Their presence can be told by the newly girdled twigs. "If the twigs are gathered and stored each year until about the first of July, then burned, all the twig girdlers contained in them will be destroyed, and meantime the egg parasites and probably some of the larval parasites will have escaped."

A bibliographical list of 18 references is appended.

Corn and cotton wireworm (Horistonotus curiatus), W. A. Thomas (South Carolina Sta. Bul. 155, pp. 3-10, pls. 7).—This preliminary report is based upon investigations conducted in 1910 in cooperation with the Bureau of Entomology of this Department. In Colleton County, where the greatest loss occasioned by wireworms is found, an area of about 16 square miles is said to be infested.

The first complaints of injury by this pest were received in the fall of 1907. It appears to be a very general feeder, attacking practically all of the farm crops examined, including corn, cotton, cowpeas, oats, rye, peanuts, and tobacco. The injury to cowpeas is occasioned by the small worms cutting off the feeding roots as fast as they appear. The injured plant throws off numerous small rootlets along the affected root and these in turn are cut off by the worms. As the attack becomes more serious the plant ceases to grow and by the first of June the root system has become a roll of short stubby roots and thickly matted rootlets, clustering closely about the main stalk. The plants mature at about one-half the normal size and usually without making any grain. In many cases they are killed outright by the first attack.

The wireworms have not been observed boring into the stalk or roots of corn. Oats and rye seem to be attacked in the same way as corn, but the loss of roots does not seem to affect these plants so vitally. "Cotton and tobacco are also similarly affected. The tender feeding roots are clipped off, and the plants die of starvation. In tobacco this occurs soon after the plants are transplanted to the field and before they are thoroughly established in the soil. Very often the young cotton plants do not reach the surface of the soil before being killed by the wireworms. In peanuts the wireworms cut off many of the feeding roots, seriously checking the growth of the plant, and when the nuts are formed in fall these are bored into and the kernel destroyed. These worms have been found working in the fruit of peanuts as late as October 21."

The eggs are deposited in the spring and the larvae hatching out feed through at least the two following summers, arriving at maturity in late spring or early summer. The adults appear to emerge late in the summer or fall and oviposit the following spring.

The most serious injury to corn appears to be caused from May 15 to June 1, that to cotton from the time it begins to come up until it has 3 or 4 leaves. In oats and rye the attack begins in the fall while the grain is very small and continues more or less throughout the winter and until it matures.

In view of the fact that the injury is confined to plants growing in light sandy soil decidedly deficient in humus, the remedial experiments conducted aimed at supplying humus to the soil and the stimulation of plant growth early in the spring. Experiments were conducted on 4 farms, a 5-acre tract on each being laid out into 10 plats and planted to corn. It was found on April 28 that on plats containing growing rye from the previous fall's sowing practically no worms were about the young corn plants, although thousands had collected about the growing rye and were rapidly destroying the root system. On plats without rye the corn was being badly attacked by the wireworms, about 40
per cent being seriously affected. On plots where stable manure and fertilizers were used the yield was at the rate of 43 bu. per acre; on plots where fertilizer alone was used the yield was at the rate of 9 bu. per acre; where rye alone was used the yield was 8 bu. per acre; and when no fertilizer or rye was used the yield was nothing.

The results indicate that the wireworms prefer feeding upon rye to feeding on corn, and that rye may be grown between the rows of corn as a trap crop until the corn has time to develop a root system sufficient to withstand their attack. It is thought that if the corn is stimulated in the early spring by the application of quick-acting fertilizers or by other means the plants will have developed a good root system before the worms can become destructive and a greater part of the injury thereby be avoided. As regards cotton, it is said that the only plot which gave a stand was the one that had been limed.

The mango weevil, C. L. Marlett (U. S. Dept. Agr., Bur. Ent. Circ. 141, pp. 3, figs. 2).—This circular calls attention to the danger of introducing the mango weevil into this country in mango seeds, the shipments of which now arriving are largely infested with the pest. See also a previous note (E. S. R., 23, p. 764).

This weevil now inhabits all of the mango-growing regions on the Indian Ocean and adjacent islands and occurs throughout the East Indies, including the Philippines and other groups of South Pacific islands, and has also gained foothold in South Africa, Madagascar, and numerous other points. Van Dine reported (E. S. R., 18, p. 355) that in Hawaii during the first year of an examination made for this pest 60 per cent of the mangoes were infested, and the following year 80 to 90 per cent, as many as 4 larvae being found in a single seed in some instances.

The egg is deposited in the fleshy part of the fruit, and the young grub burrows at once into the seed pod and develops in the seed to a pupa and finally to the adult weevil. It remains in the seed for some time and can therefore be readily distributed with seed for planting or with the ripened fruit. The green mango soon heals up over the egg slit, and there is very little, if any, exterior indication of infestation. Protected as the weevil is within the seed pod, it is beyond the reach of insecticides and fumigation. The only means of determining its presence is by opening the seed pod and removing the paper like covering of the seed itself, when the work of the larvae and weevil can be noted.

As preventive measures against the introduction of this insect the author recommends that all seeds for planting purposes be opened in this manner and where found infested burned, and that apparently sound seed be germinated in a box under a wire screen in order that any weevils which may occur in the seeds may be destroyed. It is urged that the State of Florida use whatever authority it may have to prevent or control importations of mango seeds.

Bee diseases in Ontario (Ontario Dept. Agr. Bul. 190, 1911, pp. 11).—This is a brief discussion of bee diseases, and their occurrence in Ontario.

The wheat jointworm, J. S. Houser (Ohio Sta. Bul. 226, pp. 175-201, figs. 19).—In this bulletin, which is based on observations made in 1908, 1909, and 1910, the author describes and illustrates the life history and habits of, and injury caused by, Isosoma tritici. This pest has been present in some sections of Ohio for the last 6 years, the infestation occasionally being so severe that the wheat has not been considered worth harvesting.
In all the observations made it was found that the covering leaf-sheath was pierced and the eggs deposited in the joints. In 1900 the joints high up in the straw were attacked, while in 1910 the lower ones were selected. It appears that the youngest joints are selected by instinct in order to allow the longest possible time for the development of the larva before the hardening of the straw. The author is of the opinion that the higher up the stalk is injured the less is the resulting damage that may be expected. While the larva sometimes occur singly, at other times as many as 25 will be found above a single joint, each in a single cell. Hibernation occurs in the closed larval cells, the insect being either in the larval or pupal stage. This affords an excellent opportunity for remedial measures. It is shown that moisture in the straw which contains the hibernating insects has much to do with the future of the pest. Adults forced to emerge by keeping stubble in a warm room were exposed for 19 hours on December 22 to a temperature that dropped to 10° F., without ill effect. Maps are given which indicate the localities in Ohio in which it was definitely ascertained that this pest occurred during the years 1908, 1909, and 1910.

Observations were made of the varieties of wheat affected. "Taken as a whole, the study of varieties, as pertains to the jointworm problem, indicates that one should select a wheat with a fair-sized, stiff straw, which is known to do well in his section. The stiffness prevents falling, and if the straw is fair-sized, it is believed that the presence of the jointworm larvae within its walls does not injure it to the extent that it would if the straw were undersized."

Tests of the effect of fertilizers are reported in tabular form. A study made of the 3 tests described reveals no evidence as to whether or not fertilized or unfertilized wheat is more susceptible to jointworm attack under all conditions and during various seasons. The author concludes, however, that it pays to fertilize liberally as the increased yield more than offsets the harm produced by the greater percentage of infestation which may prevail.

As regards the time of seeding the author states that at present the only dependable recommendation to be made is that the wheat be sown on that date which with average conditions has been found to yield the best crop. He thinks that the danger from straw stacks has been unduly emphasized and that the danger from old stubble has been too little considered. His observations indicate that wheat adjoining stubble is more severely infested than that grown some distance away. It was found, however, that the jointworm adults will fly at least a quarter of a mile, and it is probable that under stress they will fly much farther. Of the several species of parasites Ditropinotus aurocriviridis occurs in greatest numbers. The fungus Sporotrichum globuliferum was found during 1909 and 1910 to have destroyed great numbers of over-wintering pupe.

The burning of the stubble of the year previous is considered by all odds the easiest and most effective measure to be used against the wheat jointworm, the other remedies to be employed being "nothing more than a thorough system of progressive farm practice."

The cotton red spider, E. L. Worsham (Georgia Sta. Bul, 92, pp. 135-141, pls. 5).—The author finds that in the latitude of Atlanta the red spider (Tetranychus gloveri) passes the winter in the adult stage and even propagates sparingly at a temperature slightly above freezing.

"Repeated examinations of a cotton field at Unadilla revealed the spider present throughout the winter on green vegetation in the field, on a ditch bank, and in a marsh adjoining the field. Some few blackberry leaves remained green all winter and furnished food for great numbers of adult spiders. The common goldenrod was another important winter food plant. In fact, all green vegetation about the field, with the exception of tough-leafed plants, such as bramble brier, were found to house small colonies of spiders. The
hardiness of the spider is remarkable. In Atlanta violet leaves infested with the spiders were gathered in an ice-coated condition from open beds. When the ice thawed the spiders resumed their activities."

In experiments conducted at Unadilla during the winter it was found that in all cases where the spiders were isolated from food plants, but with otherwise normal surroundings, they all perished. "In several instances during the winter spiders were observed at the base of the plants, and even below the surface of the ground, but always on living plants. Such positions were occupied only temporarily and apparently on account of affording better protection from the cold.

"From breeding experiments conducted in the laboratory it was found that the female deposited from 1 to 12 eggs per day for a period of 6 to 10 days. Ninety-four eggs was the largest number noted as being deposited by any one female, 80 being the average in a large number of experiments. The eggs usually hatch in midsummer in 3 or 4 days, whereas at lower temperatures a week or 10 days and even longer periods of time were recorded. . . .

"Some few eggs are deposited on the upper surface of badly infested leaves, but such cases are exceptions rather than the rule. The young at first have 6 legs, but after the first molt they have 8. They molt twice before they are fully grown. Usually from 9 to 14 days are consumed in reaching the adult stage. In all, 3 or 4 weeks cover the entire life cycle of individual spiders during the summer. In cotton fields the spiders seldom become numerous enough to attract attention until the first of July."

As a result of the removal of the juice from cotton leaves slight yellow spots appear on the surface which, as the feeding progresses and infestation becomes more severe, enlarge and the leaves begin to curl. Gradually the leaf turns reddish brown in color. Cotton thus attacked has a rusty red color in its final stage.

"Cotton and peas are by far the most seriously injured staple crops, and the spiders always discriminate in favor of them where a selection of food plants is to be had. . . . Of the greenhouse and ornamental plants attacked, violets perhaps rank first. Chrysanthemums, carnations, and the morning glory are close seconds. Roses are not so seriously affected. Violet beds housing over-winter adults were so badly infested by the middle of April as to present the appearance of having been scorched. . . . In vegetable gardens and on truck farms beans, tomatoes, cucumbers, and watermelons are attacked. The two former are very susceptible to red spider injury. At Unadilla, Ga., in the late summer beans and tomatoes were observed stripped of their foliage by the pests." No deciduous fruit trees were observed to be attacked even when readily accessible to the spiders and their more desirable food was scarce.

The lady beetle Stethorus punctum was the only natural enemy of this pest observed, both the larvae and adult beetles feeding upon the spiders as well as their eggs.

"Of 14 sprays tested 3, viz, the lime-sulphur solution, Scalecide, and soap solution, gave very satisfactory results. The remaining sulphur compounds were more or less beneficial, but not to a degree to warrant recommendation. The lye solution and tobacco teas were practically worthless. The soap solution killed from 83 to 92 per cent of the spiders, but very few, if any, eggs. Both the lime-sulphur and Scalecide solutions gave admirable results, killing over 99 per cent of the spiders as well as the eggs. No injurious effect was apparent from any of the sprays."

Since the adult spiders pass the winter on green vegetation it is recommended that the winter food plants be destroyed by practicing fall plowing in infested
areas. "Ditch banks should be thoroughly cleaned of green vegetation during the winter. The more nearly all winter food plants are destroyed in close proximity to infested cotton fields the more unlikely they will be to become infested the following year."

Studies on the biology of the Texas fever tick, H. W. Graybill (U. S. Dept. Agr., Bur. Anim. Indus. Bul. 130, pp. 7-52, tables 2, figs. 3).—This bulletin is based upon studies conducted at Auburn, Ala., during 1907-8 in cooperation with the veterinary department of the Alabama Station.

Following a brief account of the history of biological studies of this tick, the author describes his methods of study. Under periods of the nonparasitic portion of development, studies of the preoviposition, oviposition, incubation, hatching, and longevity periods are reported upon. Then follow accounts of the number of eggs laid and percentage hatched, experiments with horizontal tubes, records obtained from the field plats, percentage of females ovipositing, effect of immersion in water on engorged females, the influence of moisture on the incubation period, periods in the parasitic portion of development, observations on the movement of ticks after the first and second molt, early distinguishing of females by males, experiments in transferring ticks on cattle, experiments on rearing unfertilized females, the occurrence of dead ticks on cattle, and the host relations of the cattle tick.

A bibliography of 22 titles is followed by an appendix consisting of 2 tables, the first on individual records of ticks used in the experiments and the second giving data on parasitic development of the ticks on animals.

Some of the more important ticks of the United States, W. D. Hunter and F. C. Bischoff (U. S. Dept. Agr. Yearbook 1910, pp. 219-230, pls. 2).—This paper gives brief accounts of 10 of the more important ticks that occur in this country.

FOODS—HUMAN NUTRITION.

[Experiments with wheat and flour], R. Harcourt (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 36 (1910), pp. 81-98).—In a study of Nos. 1 and 2 grades of northern wheat of the crop of 1910, in comparison with 1909 wheat, it was found that the water absorption in the new wheat was lower, "but that is only natural when new wheat is compared with old wheat that had been kept in a dry place for 12 months. In all other respects the flour from the new wheat is fully equal to that from the old wheat, and, when we consider the advantage due to aging of the latter, it is plainly evident that the miller has nothing to fear in milling the wheat of the 1910 crop."

From baking tests with a number of varieties of Ontario spring wheats, the author concludes that "without trying to give too much importance to these baking tests of one year's crop, it may be pointed out that Early Java gave the best all-around results, while French, Gatineau, Red and White Fife, White Russian, and Preston Springs gave results which compared wonderfully well with the Manitoba-grown Standard."

A large number of baking tests with Ontario-grown winter wheats of 1909-10 showed that there were some wide variations in the qualities of the wheats of the two seasons, the most notable point of difference being in the percentage of wet gluten, the amount being in general less in the 1910 crop than in wheats grown the preceding year. However, the author concludes that "although there is such a wide difference in some respects, the two crops are not very far apart in the quality of the bread they will produce."

The results obtained with carbon bisulphid, hydrocyanic-acid gas, and sulphur as mill fumigants are noted below from another source.
Some additional data are reported regarding the nature of a commercial substance recommended for fumigating flour mills. A chemical analysis showed that this material contained nicotine and other forms of alkaloids. There was no opportunity to determine its efficiency in destroying insects in mills, but the author was "unable to find that it did any injury to the flour. The strong smell of burning tobacco noticeable on the flour did not quickly disappear, and was evident in the bread made from heavily treated flour even 3 weeks after treatment. Otherwise the bread was in every respect equal to that made from the untreated flour."

Investigations on the effects of bleaching flour are also summarized and discussed. According to the author, the results obtained lead to the belief that "bleaching flour with the oxids of nitrogen produced by the electrical method whiten the flour and slightly improves the texture and appearance of the loaf. This difference is more pronounced with the flour from new wheat than with that from older wheat. The color obtained as a result of the treatment with the gas is whiter, but to many people it is not so desirable as the creamy tint of the normally aged flour. There does not appear to be much difference in the water absorption; in fact, in all our work we get rather lower absorption. The volume of the loaf is slightly increased, and, naturally, as the bleaching is a process of aging, the increase in volume is most noticeable in the flour from new wheat. To sum up, it would appear that bleaching has some of the effect of time in improving flour, but does not give the full results of 'aging' produced by time."

For earlier work see a previous note (E. S. R., 23, p. 308).

Effect of mill fumigants upon flour, R. Harcourt (Northwest. Miller, 83 (1910), No. 11, pp. 661, 662, figs. 6).—As a contribution to the question of mill fumigation for the destruction of insects the author carried on investigations on the influence of hydrocyanic acid, carbon bisulphid, and sulphur fumes upon the composition and baking quality of flour.

Treatment with hydrocyanic-acid gas, under the experimental conditions, did not destroy the bread-making quality, while treatment with carbon bisulphid and sulphur fumes resulted in darker loaves, poorer in texture and in general appearance. The author further concludes that treatment with hydrocyanic acid and carbon bisulphid vapor did not materially affect the production of alcohol-soluble or water-soluble proteids, but that in both hard and soft wheat flour the sulphur treatment materially increased the amount of water-soluble proteids. This was especially true of the soft-wheat flour. "The water-soluble proteids were also increased slightly by the carbon bisulphid treatment, both in the hard and soft flour, but more particularly in the latter. . . .

"The acidity of the flours was also influenced, more particularly, as would be expected, by the sulphur fumes, and possibly it is this factor, together with its effects on the gluten, which most seriously injures the sulphur-treated flour."

The effects of fumigants on the bacteriological life of flour were also studied, hydrocyanic acid showing no reduction in micro-organisms, carbon bisulphid a slight reduction, and sulphur-treated flour a great reduction.

"From the above results, it is very evident that carbon bisulphid would be very much more injurious to flour than hydrocyanic acid. The results were not continued long enough to ascertain how long the carbon-bisulphid-treated flour would be in getting back to normal condition, but the experiment was discontinued because it was felt that, if flour would not become normal in 4 or 5 months from time of treatment, it would practically be as fatal to the miller as if it never would regain its original condition."
"The carbon bisulphid is very effective in destroying insect life, but it is evident that, if this material is to be used as a fumigant, all wheat or flour must be removed from the mill before the fumigation is done."

The author points out that precautions must also be exercised in the use of the materials under consideration, owing to their poisonous properties.

A preliminary note on the nutritive value of white and of standard bread, L. Hill (Brit. Med. Jour., 1911, No. 2627, pp. 1068, 1069).—White and so-called "standard" bread were compared in tests with rats (2 lots of 25 each) fed exclusively on such breads or flour and water for 6 weeks. The total gain on white flour was 114 gm. and on standard flour (i.e., flour containing sufficient germ and bran products to make it represent 80 per cent of the original wheat berry) 278 gm. Ten of the rats fed white flour, originally included in the test, died, as compared with 5 fed on the standard flour bread.

The author states that he fed another lot on white flour plus an amount of wheat germ about equal to that in standard flour and obtained results as good as those with such flour.

When pancreatic digestion tests were made the standard flour gave the Adamklewicz reaction for tryptophane earlier, "showing that this essential amino acid is split off earlier, and therefore is probably better absorbed in the intestine and utilized in the body."

Tests in which 15 individuals chewed a weighed quantity of 2 sorts of flour for 2 minutes did not show any differences in acidity.

According to the author, "It seems clear that either our standard flours contained something essential to growth which was not in our white flours, or that the white flours contained something detrimental—for example, improvers. . . .

"It is highly probable that the germ, the growing part of the wheat grain, would contain amino acid groupings essential for growth, and possibly bodies which activate the enzymes engaged in the digestion of the proteins of wheat. Treatment of the white flour may have destroyed these bodies. . . .

"It seems clear that children of the poor, who are largely fed on bread and margarine or bread and jam, ought to have the standard and not the white bread tested by us. How far the results are due to treatment of our white flours by 'bleaching,' etc., we are not able to say, and we can not therefore generalize that all white flours are worse than standard."

Comparative nutritive value of white and standard bread, E. S. Edie and G. C. E. Simpson (Brit. Med. Jour., 1911, No. 2628, p. 1151).—From tests with pigeons, which are briefly reported, the conclusion was reached that standard or whole meal bread is superior to white bread.

The results are discussed in connection with the work by L. Hill reported above.

Comparative nutritive value of white and standard bread, C. Watson (Brit. Med. Jour., 1911, No. 2628, p. 1151).—In a critical discussion of the paper by L. Hill, noted above, the author states that in experiments which he carried on with rats fed white and standard bread no appreciable differences could be observed which could be attributed to the kind of bread.

The bread supply of France, B. F. Yost (Daily Cons. and Trade Rpts. [U. S.], 13 (1910), No. 136, pp. 1132-1134).—Statistical and other data are summarized in this brief discussion of the subject.

The formation of albuminoses in meat products, Maurel and Arnaud (Compt. Rend. Soc. Biol. [Paris], 79 (1911), No. 16, pp. 709-711).—Analytical studies of pâtés and sausage showed that such goods often contained albuminose when fresh. This is probably in part at least derived from gelatin and is due
to bacterial action. The data are discussed with reference to the matter of food poisoning.

In general, he concludes that there is much variation in the amount of edible material in fish, regardless of the method of preserving or cooking, the range noted being from 48 to 95.2 per cent. Those methods of handling fish are to be preferred which involve the least labor, as boiling, or those in which the fish is marketed ready for use, as smoking, pickling, salting, frying, marinating, and cooking in oil or in a jelly. When fish was boiled a loss was noted in all classes of nutrients. When baked, lean fish gained in fat content, owing to the added fat, and fried fish gained in nutritive value, owing to the flour or bread used in preparing it. Salting, pickling, smoking, and marinating all lessened the several nutrients in the fresh fish flesh. In general, the conclusion was reached that all methods of preparation lessened the amount of nutritive material originally present. The experimental data are discussed in detail.

Cheese and other substitutes for meat in the diet, C. F. Langworthy (U. S. Dept. Agr. Yearbook 1910, pp. 359-370).—The possibility is discussed of using fish, eggs and milk, dried beans and other legumes, nuts and nut products, commercial meat substitutes, mushrooms and other edible fungi, and cheese, in place of meat, in suitable combination with other foods, in order that a palatable diet may be secured, special attention being paid to cheese and cheese dishes. The summary is based on extended investigations carried on in connection with the nutrition investigations of this Office.

On the blanching of vegetables (Pure Products, 7 (1911), No. 6, pp. 318-320).—A considerable amount of data is summarized regarding the relative losses sustained in steam-cooked vegetables in comparison with those cooked in hot water. See also a previous note by Maurel and Carcassagne (E. S. R., 22, p. 308).

[A new asparagus product] (Pure Products, 7 (1911), No. 6, p. 320).—A product designed for use in making asparagus soups and similar dishes is described, which is prepared by separating the soft pulp from the fiber of fresh asparagus and preserving it in cans in the form of a thick paste.

Studies of the more important legumes cultivated in Togo and German East Africa, C. Grimm (Ztschr. Untersuch. Nahr. u. Genussmittel, 21 (1911), No. 9 pp. 577-553).—Analyses of mungo beans, lablab beans, cowpeas, and other legumes are reported in comparison with earlier work.

The basic extractives of mushrooms, F. Kutscher (Ztschr. Untersuch. Nahr. u. Genussmittel, 21 (1911), No. 9, pp. 535-540).—Cholin and betain were identified. The chief basic material present was probably potassium. The results are discussed in relation to invalid dietetics. See also a previous note (E. S. R., 24, p. 665).

Pentosans in lower fungi, A. W. Dox and R. E. Neidig (Jour. Biol. Chem., 9 (1911), No. 3-4, pp. 267-269).—From studies with Aspergillus niger and 5 other common saprophytic molds, the conclusion was reached that pentosans "are normal constituents of the cell structure of lower fungi and are formed independently of the presence of penose complexes in the culture medium."

The results also indicated that not more than traces of purins could have been present.
A comparative study of grapes from frozen and unfrozen vines, Hugues (Ann. Falsif., 4 (1911), Nos. 30, pp. 175, 176; 31, p. 258).—The data reported had to do particularly with the yield and character of grapes and the resulting wine from frozen and protected vines.

Dried grapes in Greece, L. Roos (Ann. Falsif., 4 (1911), Nos. 29, pp. 113–126; 31, p. 258).—A summary of data regarding the dried grape industry in Greece.

A study of the composition of Hawaiian pineapples, W. P. Kelley (Jour. Indus. and Engin. Chem., 3 (1911), No. 6, pp. 403–405).—The pineapples analyzed were found to vary considerably in composition, the sugar content ranging from 9.15 to 15.23 per cent, and the acidity from 0.22 to 1.16 per cent, and increasing generally as the sugar increased. On the whole Hawaiian pineapples show much the same average composition as those grown elsewhere.

"Green pineapples contain less acidity than the ripe fruit and also a small percentage of fiber, reducing sugar, and sucrose. Dextrin and starch do not occur in important quantities in pineapples at any stage. The reducing sugars and sucrose stand in inverse ratio to that of the ripe fruit. In the ripening of pineapples gathered green the most important chemical change that takes place is the conversion of reducing sugars into sucrose, but the total sugar content appears not to be increased.

"The cells of green pineapples as seen under the high-power microscope contain a thickened layer on the cell walls, which renders it difficult to express the juice from the cells. In the ripening process this layer gradually becomes dissolved away, until at maturity the cell walls are extremely thin and easily ruptured. With pineapples that are gathered green and allowed to ripen the thickened coat on the cell walls also becomes dissolved, thus apparently increasing the juice in the fruit but without materially changing its concentration.

"During the normal ripening of the pineapple a rapid accumulation of sugars and a slight increase in acidity takes place. When the fruit becomes approximately half ripe, it contains at least three-fourths of its maximum sugars."

Classification of ice cream and related frozen products—score card for ice cream judging, M. Mortensen (Iowa Sta. Bul. 123, pp. 353–365, fig. 1).—On the basis of a summary of data the author classifies ice creams as follows: (1) Plain ice creams; (2) nut ice creams; (3) fruit ice creams; (4) bisque ice creams; (5) parfaits; (6) mousses; (7) puddings; (8) aufts; (9) lactos; and (10) ices. The last section is subdivided into sherbets, milk sherbets, frappes, punches, and soufflés.

A number of formulas for making ice cream are given and a score card is proposed for judging the quality of ice cream.

The contamination of ice cream—a sanitary and bacteriological study, G. F. Buchan (Jour. Hyyg. [Cambridge], 10 (1910), No. 1, pp. 93–130, pl. 1).—The author reports the results of a sanitary and bacteriological study of the ice cream industry in England, and of numerous investigations. The premises of 50 ice cream manufactories were inspected, their methods investigated, and bacteriological examinations made of samples taken immediately before heating the ice cream mixture, after cooling, and after freezing.

In general he did not find that the trade was carried on under conditions or with precautions necessary to insure a clean product. The bacteriological pollution of ice cream he considered is due to insufficient initial heating, or to contamination during cooling and freezing from "unclean vessels and covers, the addition of unclean ice to hasten freezing, the unclean hands of the manufacturer, and dirty surroundings."

Brief directions are given for the sanitary manufacture of ice cream, and bacteriological standards are suggested.
Cotton-seed oil as a food for man, H. W. Wiley (Nat. Provisioner, 44 (1911), No. 23, pp. 28-33, figs. 12).—The importance of cotton-seed oil as food for man is emphasized and suggestions made for increasing its use. The author regards it as a wholesome and valuable fat food.

Preservatives in food, H. E. Davies (Jour. Roy. Inst. Pub. Health, 19 (1911), No. 5, pp. 288-292).—In this discussion of the question of preservatives the author summarizes some of his own work, particularly that which has to do with the detection of unusual preservatives, as sodium peroxid in milk and flourin compounds. He points out that in general an attempt is being made to use preservatives "which will evade the skill of the public analyst."

Inspection of imported food and drug products, R. E. Doolittle (U. S. Dept. Agr. Yearbook 1910, pp. 201-212).—Laws regarding imported food and drug products, their inspection by the Department of Agriculture, inspection procedure, and imported foods and drugs and their sophistication are the principal topics considered in this summary and discussion of the subject.

Report of the chemist, J. Hortvet (Bicm. Rpt. Minn. State Dairy and Food Comr., 13 (1909-10), pp. 191-261).—Out of a total of 4,193 samples of canned fruits and vegetables, cheese, dairy products, alcoholic liquors, miscellaneous food products, and white lead and mixed paints which were examined, 2,013 samples were declared illegal.

The handling, transportation, and storage of perishable foodstuffs. J. S. Hepburn (Jour. Franklin Inst., 171 (1911), No. 6, pp. 585-598, figs. 7).—A digest of data, particularly relating to the work of the food research laboratory of the Bureau of Chemistry of this Department.

Wholesale prices, 1890 to March. 1910 (U. S. Dept. Com. and Labor, Bur. Labor Bul. 87, pp. V+377-708, dgms. 4).—A large amount of statistical data regarding prices of foods and other commodities is summarized, as well as information regarding the cost of living, earnings, and hours of labor in European countries. A paper entitled Wages and Hours of Labor of Union Carpenters in the United States and in English-Speaking Foreign Countries, by E. Stewart, is included, and a number of court decisions affecting labor are given.

Cost of living in Germany, 1907–8 (U. S. Dept. Com. and Labor, Bur. Labor Bul. 88, pp. V+697-926+X).—Statistical and other data regarding the cost of living of families of moderate income in Germany in 1907-8, and wages and hours of labor in Germany and Austria, are included in this bulletin, as well as a digest of recent reports of state bureaus of labor statistics and of recent foreign statistical publications, and also decisions of courts affecting labor.

Some observations on diet in India, B. N. Ghosh (Jour. Roy. Inst. Pub. Health, 19 (1911), No. 5, pp. 293-299; Diet. and Hgy. Gaz., 27 (1911), No. 8, pp. 470-475).—In connection with a critical discussion of studies of diet in India, particularly McCay's work (E. S. R., 25, p. 167), the author suggests dietaries for natives and for Europeans, and especially recommends the use of milk products in the native diet.

Some features of nutrition during growth, L. B. Mendel (Jour. Home Econ., 3 (1911), No. 3, pp. 262-268).—A summary and digest of data, with a general discussion of diet during infancy and childhood.

What to eat and why, G. C. Smith (Philadelphia and London, 1911, pp. 310).—Diet in relation to disease of various sorts is discussed in this volume, designed particularly for medical students and for practitioners. In addition to specific directions for arranging various diets, the author discusses such
general questions as the composition of food, the principles underlying its use, and the scientific reasons why a change of diet is desirable in certain diseases and ways for arranging such special diets in a practical manner.

Good things to eat, R. Estes (Chicago, 1911, pp. 1½, pl. 1).—A large number of recipes are given for soups, meat and fish dishes, vegetables, desserts, etc.

The book embodies the author's practical experience in connection with dining-car and restaurant cookery, and it is noticeable that many of the dishes can be prepared from such stores as might be part of the equipment of a dining car.

The successful home cook, Lucy H. Yates (London [1910], pp. VIII+248).—Many recipes are included for pastry and desserts as well as for meat dishes, though the bulk of the volume is devoted to a discussion of methods of preparing food and to the consideration of general housekeeping problems.

This book is written from the standpoint of English methods of housekeeping. However, the author's discussions of economy and other topics are of general application.

The respiration calorimeter and the results of experiments with it, C. F. Langworthy and R. D. Milner (U. S. Dept. Agr. Yearbook 1910, pp. 307-318, pls. 2).—The construction and operation of the respiration calorimeter in its improved form are described.

"As regards construction, the distinguishing feature of the apparatus is an air-tight and heat-tight metal-walled chamber, with outer insulating walls, which is of a size suitable for experiments with man. The chamber is equipped with conveniences so that the subject may remain in it for long periods if need be. Air circulation through the apparatus is provided for, the respiration products being removed and oxygen added as required. The respiratory products and other excretory products are measured and analyzed in comparison with the food supply, the oxygen consumption is determined, and also the total energy (i.e., heat) output of the body. With this apparatus it is therefore possible to study the complete balance of income and outgo of matter and energy in the body, to measure the respiratory quotient—that is, the ratio between oxygen consumption and carbon dioxide excretion—and to study other indexes of body change.

"Control tests have shown that even in experiments of long duration the measurements which are made are as accurate as those obtained in the analysis of small quantities of material by the usual laboratory methods. It seems fair to conclude that the respiration calorimeter is to be regarded as an instrument of precision, useful for the study of everyday problems as well as those of scientific interest."

See also a previous account (E. S. R., 24, p. 601).

A method for determining the total respiratory exchange in man, C. G. Douglas (Jour. Physiol., 42 (1911), No. 4, pp. XVII, XVIII, digm. 1).—The author describes a mouthpiece and gas bag for collecting respiratory products, which may be worn by the subject, and designed for experiments of short duration. The advantages claimed are the lightness of the apparatus, its portability, ease of adjustment to the subject, and the fact that "the necessary manipulations can be done by the subject himself without external help. The method is equally adapted for determining the total respiratory exchange during rest and under conditions of even violent muscular work, such as running, and is particularly suitable for the examination of clinical cases."

The increase in metabolism due to the work of typewriting, T. M. Carpenter (Jour. Biol. Chem., 9 (1911), No. 3-4, pp. 231-266).—Continuing earlier work (E. S. R., 21, p. 568), respiration calorimeter experiments were made with 5 subjects, including both men and women.
According to the author's summary, during typewriting at the rate of 57 to 115 words per minute, there was an increase of pulse rate from 90 to about 120 and in respiration from 19 to 30, as well as an increase in body temperature. The work of typewriting resulted in an increase of from 30 to 70 per cent of the total metabolism, or, on an average, about 50 per cent above metabolism at rest.

"The amount of increased energy above the resting metabolism per 1,000 words was on the average about 7 calories and the increase in both the carbon dioxide and the oxygen was 2.5 gm.

"The increase in carbon dioxide and oxygen due to 1,000 strokes upon a typewriter was 0.57 and 0.54 gm., respectively, and about 1.6 calories increase in energy output.

"The measure of metabolism by periods during the work of typewriting shows that there was a gradual decrease in the amount of energy required per 1,000 strokes. This was more marked in the individuals whose hands and fingers became extremely tired, which would indicate that during fatigue, work is accomplished more economically.

"The average equivalent amount of work calculated from the increase in metabolism in these experiments varied from 1,950 to 4,000 kgm. per hour and the calculation based upon these results gave an average of 145 kgm. per 1,000 strokes of typewriting.

"The variation in the increase in metabolism due to the work of typewriting in these different individuals is considered to be due to differences in individual facility and technique. The female subjects showed a more uniform increase than the 2 male subjects who represented the extremes in these experiments."

Motion study—a method for increasing the efficiency of the workman, F. B. Gilbreth (New York, 1911, pp. XXIII+116+32, figs. 44).—In this discussion of efficiency in labor the author gives a description and general outline of motion study and considers at length variables of the worker, of the surroundings, and of the motion, and also the past, present, and future of motion study. Health, modes of living, nutrition, body size, training, and experience are among the variables of the worker which the author discusses.

As the author points out, "the aim of motion study is to find and perpetuate the scheme of perfection. There are three stages in this study: Discovering and classifying the best practice; deducing the laws; and applying the laws to standardize practice, either for the purpose of increasing output or decreasing hours of labor, or both."

R. T. Kent contributes an introduction to the volume.

Some observations upon the deep temperature of the human body at rest and after muscular exertion, N. D. Hardswell and J. E. Chapman (Brit. Med. Jour., 1911, No. 2628, pp. 1106-1110, dgm. 1).—The temperature measurements were made with subjects at rest and walking and running for different distances and at different speeds. The recorded data show that in general there was a rise in temperature with normal individuals as a result of exercise. Though undertaken in connection especially with the subject of temperatures in tuberculosis, the work is of general interest.

Digestive leucocytosis after the ingestion of raw or cooked meat, P. Las-sablier and C. Richet (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 15, pp. 637-639).—The data reported and discussed were obtained in experiments with dogs and have to do with the increased number of leucocytes observed after eating meat and with the phenomena of alimentary anaphylaxis.

9204—No. 6-11——6
Digestion and assimilation of raw starch of different sorts in the normal and pathological digestive tract, L. Fofanow (Ztschr. Klin. Med., 72 (1911), No. 3-4, p. 257; abs. in Zentral. Biochem. u. Biophys., 11 (1911), No. 13-14, pp. 556, 557).—According to the author’s conclusions, no differences were observed in the digestion and resorption of wheat, oat, and rice starch, 50 gm. being almost completely resorbed in the normal digestive tract. Raw potato starch was from 2.5 to 4 times less well digested, the digestion and resorption being particularly bad when the starch was taken in the form of isolated starch cells with their covering of cellulose.

Regarding the effects of various pathological conditions, it may be noted that the author concludes that in cases of fermentative dyspepsia raw starch of any sort is much less well digested than when taken baked or boiled. This was particularly true of the isolated potato starch cells.

Studies on water drinking.—V, Intestinal putrefaction during copious and moderate water drinking with meals, W. M. Hathrem and P. B. Hawk (Arch. Int. Med., 7 (1911), No. 5, pp. 610-623).—According to the experimental data reported, the drinking of copious amounts of water (1,000 cc.) and moderate amounts (500 cc.) decreased intestinal putrefaction, “as measured by the urinary indican output.

“Copious water drinking caused a more pronounced lessening of the putrefactive processes than did the moderate water drinking.

“In copious water drinking the total ethereal sulphate output was increased coincidently with the decrease in the indican output. This observation furnishes strong evidence in favor of the view that indican has an origin different from that of the other ethereal sulphates, and that they can not correctly be considered as indexes of the same metabolic process. . . .

“The decreased intestinal putrefaction brought about through the ingestion of moderate or copious quantities of water at mealtime is probably due to a diminution of the activity of indol-forming bacteria, following the accelerated absorption of the products of protein digestion and the passage of excessive amounts of strongly acid chyme into the intestine.”

Data are also given regarding experimental methods.

Experiments on the relation of nitrogen to sulphur in metabolism, O. Gross (Ztschr. Exptl. Path. u. Ther., 9 (1911), No. 1, pp. 171-189 dsms., 10).—The effect of feeding lecithin was one of the questions considered in the extended investigations reported on the income and outgo of nitrogen and sulphur.

The metabolism of manganese and the law regarding manganese and iron minimum, G. M. Piccinini (Arch. Farmacol. Sper. e Sci. Aff., 10 (1910), No. 9-10, pp. 419-436; abs. in Chem. Zentral., 11, I, No. 11, pp. 823, 824).—Manganese is found in the human body and in the lower animals in small and variable quantities. It is derived from animal food and in smaller amounts from vegetable food.

When given to a dog per os manganese was resorbed from the digestive tract and stored in the liver, kidney, spleen, and intestinal wall. Manganese is excreted chiefly in gall and through the intestinal mucus membrane, and in much smaller quantity in the urine. The administration of manganese caused an increase in the iron content of the blood, liver, and spleen. Since manganese forms an integral constituent of the red blood corpuscles it is to be regarded as directly concerned in the formation of hematogen. Manganese regulates the absorption of iron and also the total assimilation.

A contribution to the etiology of beriberi, S. Kajura and O. Rosenheim (Jour. Hyg. [Cambridge], 10 (1910), No. 1, pp. 49-55, pl. 1).—The experiments reported on the relation of rice diet to beriberi were made with poultry.
The conclusion was reached that a disease very similar to beriberi can be produced by a diet of peeled rice, independently of climate or locality. "This fact seems to be of importance for the physiology and hygiene of nutrition, demonstrating the inefficiency of an exclusive rice diet to sustain life."

The experiments further led to the conclusion that the alcohol-soluble proteid of barley, at any rate in the quantities used, did not prevent the disease, and that the beneficial action of barley, when added to a rice diet, was due to some other constituent of this cereal.

"The addition to a rice diet of large quantities of calcium and of phosphorous (as calcium carbonate and calcium phosphate) seems also unable to prevent the disease."

Experiments with salts of aluminium and beryllium, W. J. Gies (Jour. Pharmacol. and Exp. Ther., 2 (1911), No. 4, p. 403).—A preliminary note on work reported below.

On the absorption of aluminium from aluminiized food, M. Steel (Amer. Jour. Physiol., 28 (1911), No. 2, pp. 91-102).—When alum was administered in aluminiun-free foods to dogs or when they were given biscuits baked with alum baking powder, "aluminium in comparatively large amounts promptly passed into the blood."

"Absorbed aluminium circulated freely, but as it did not show any pronounced tendency to accumulate in the blood, its full effects must have been registered outside of the circulation."

When aluminium chlorid was administered intravenously, from 5.55 to 11.11 per cent of the aluminium passed from the blood into the feces during the 3 days immediately following the injection. "Whether the aluminium passed directly through the walls of the intestine or was excreted by the liver, or whether both channels (or others) were followed, has not yet been ascertained."

Deterioration of aluminium and aluminum utensils, E. Heyn and O. Bauer (Mitt. K. Materialprüfungsamt Gross-Lichterfelde West, 29 (1911), No. 1, pp. 2-28; abs. in Chem. Zentbl., 1911, I, No. 12, p. 913).—The results are reported of a chemical study of deterioration in aluminum utensils, in which the solubility in water and various solutions was especially studied. Treatment with vaseline diminishes the effect of tap water and similar solutions.

**ANIMAL PRODUCTION.**

Mendelism, R. C. Punnett (New York, 1911, 3. cd., rev. and enl., pp. XIV+192, pls. 7, figs. 35).—A new and enlarged edition of a lucid exposition of Mendel's law. The revision includes results of investigations since the previous edition was issued.

Computation of the coefficient of correlation, H. S. Jennings (Amer. Nat., 45 (1911), No. 535, p. 413).—A note which suggests an easy method for reducing the large product numbers resulting in the method proposed by Harris (E. S. R., 24, p. 375) in computing the coefficient of correlation.

On sex chromosomes in hermaphroditism, W. E. Castle (Amer. Nat., 45 (1911), No. 535, pp. 425-430).—The author makes use of the recent studies of Boveri and Schleidt with parthenogenetic invertebrates to show how they provide a way of reconciling the opposed views that sex determination is independent of environmental influences and that it is dependent upon them, although he finds no positive evidence that environmental agencies control sex in the higher animals.

---

\(b\) Ber. Naturf. Gesell. Freiburg, 19 (1911).
Germ-cell determinants and their significance, R. W. Hegner (Amer. Nat., 37 (1911), No. 555, pp. 385-397, figs. 6).—Pole disk granules are called germ cell determinants because only those cells which gather in the granules become germ cells. Several hypotheses concerning their origin and significance are suggested. "The attention of investigators ought to be directed toward the problem of discovering the origin and complete history of these bodies since their bearing upon the theories of heredity is of fundamental importance."

A bibliography is appended.

The effect on breeding of the removal of the prostate gland or of the vesiculae seminales, or of both; together with observations on the condition of the testes after such operations on white rats, G. Walker (Johns Hopkins Hosp. Rpts., 16 (1911), pp. 223-235, pl. 1).—The excision of the prostate glands, or of the seminal vesicles, or both, in white rats did not in all cases affect the structure of the testes. When both were removed they failed to breed, although spermatozoa were found, but when only one of the organs was removed they produced offspring, indicating that one organ could replace to some extent the function of the other. "Excision of the prostate did not have any effect on the structure or function of the seminal vesicles."

Studies in the experimental analysis of sex, G. Smith (Quart. Jour. Micros. Sci. [London], n. ser., 55 (1910), No. 218, pp. 225-249, pl. 1; 56 (1911), No. 223, pp. 591-612).—The author has continued the studies along the line previously noted (E. S. R., 23, p. 173). A case is also reported in which intestinal tuberculosis caused a degeneration of the reproductive organs of a cockerel, accompanied by atrophy of the sexual characters, but without approaching those of the female, which is in accord with the theory of sex-limited inheritance.

The injection of testes extract into hens was found to have an entirely negative effect on the increase of the comb in 8 out of 9 adult and young hens, when compared with the fluctuations in the growth observed in control birds. The injections had no observable effect on the health, body weight, fertility, blood properties, or other features, although large quantities were administered over periods varying from 15 to 75 days.

Inspection of commercial feed stuffs, P. H. Smith et al. (Massachusetts Sta. Bul., 136, pp. 3-56).—This contains results of feed inspection in 1910, with comments thereon. Analyses reported include cottonseed meal, linseed meal, gluten feed, dried brewers' grains, malt sprouts, distillers' dried grains, clover meal, alfalfa meal, wheat by-products, rye meal, bone meal, meat scraps, corn meal, hominy meal, oats, provender, fortified starchy feeds, corn bran, dried-beet pulp, clover and alfalfa meals, and proprietary mixed feeds.

Analyses of commercial feeding stuffs sold in Maryland (Md. Agr. Col. Quart., 1911, No. 52, pp. 6).—Analyses are reported of cottonseed and linseed meals, gluten feed, beet pulp, distillers' grains, meat meal, beef scrap, molasses feeds, and proprietary poultry and mixed feeds.

Concentrated commercial feeding stuffs (Dept. Agr. Tenn. Buls. 1, 1910, pp. 88; 2, 1911, pp. 93).—Analyses are reported of wheat by-products, corn bran, hominy feed, cottonseed meal, dried brewers' grains, malt sprouts, beef scrap, dried-beet pulp, alfalfa meal, linseed meal, chicken feeds, and proprietary mixed feeds.

[Analyses of cattle feeds], R. Harcourt (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 36 (1910), pp. 77-79).—Analyses are reported of 74 samples of
cattle feeds, including corn, wheat, oat, barley, and flax products, linseed cake, linseed meal, mixed feeds, pea meal, rice meal, molasses feeds, proprietary feeds, and silage. The requirements of the Commercial Feeding Stuffs Act, which came into force January 1, 1910, are noted.

Study of the conservation of olive residue, R. Marcille (Bul. Div. Agr. Com. et Colon, [Tunis], 14 (1910), No. 57, pp. 476–482).—Experiments are reported with formalin, sulphurous acid, and other antiseptics to prevent fermentation and the growth of molds on the residue of the olive press when used for stock feed.

Feeding experiments, W. Schneiderwind, D. Meyer, and Gröbler (Landw. Jahrb., 39 (1910), Ergänzungab, 3, pp. 161–195, 206, 297).—In rations for swine containing steamed potatoes, barley, and fish meal the best gains were made with a high protein content in the early part and with a low protein content in the latter part of the feeding period. The average gain per head and day with a high protein content was 0.63 kg., at a cost of 0.5117 marks (about 8.8 cts. per pound); on a medium protein content, 0.64 kg., at a cost of 0.493 marks; and on a low protein content, 0.65 kg., at a cost of 0.560 marks. When soy beans were substituted for the fish meal the corresponding gain with a high protein content was 0.58 kg., at a cost of 0.5179 marks. The percentages of dressed weight for the 4 lots were 50.4, 51.2, and 59.4, respectively.

Beet chips were found to be much inferior to dried potatoes, and are not recommended in rations for swine. Other experiments with dried potatoes have been noted from another source (E. S. R., 21, p. 472).

Fattening cattle were found to do equally well whether tied in a common stall or when at liberty in a box stall.

Pine needles when made a part of the ration for wethers compared very unfavorably with bran or meadow hay.

The analyses of feeds used are given.

Fattening steers of different ages, J. W. Wilson (South Dakota Sta. Bul. 125, pp. 69–72, figs. 6).—This experiment was undertaken to ascertain the gains made by steers of the same quality, under the same conditions, and with the same kind of grain rations, but of different ages, and also to test the effect of age of steers on the production of pork with pigs following.

The cattle consisted of 2 lots each, 6 to the lot, of yearlings, 2-year-old, and 3-year-old steers. One lot of each age was home-bred and the other range-bred cattle. The feed, which was the same for each lot, consisted of upland prairie hay, shelled corn, and linseed meal. One-tenth as much linseed meal was given each lot as it would eat of shelled corn, and all the hay that was wanted. Enough pigs were put in each yard to pick up the waste. The tests lasted 127 days.

In the home-bred lots the 3-year-olds made an average daily gain of 2.52 lbs. and consumed 7.42 lbs. of corn, 5.81 lbs. of hay, and 0.73 lb. of linseed meal per pound of gain; the 2-year-olds averaged 2.59 lbs. gain daily and consumed 6.53 lbs. of corn, 5.8 lbs. of hay, and 0.64 lb. of linseed meal for each pound of gain; the yearlings made a daily gain of 2.48 lbs., and for each pound of gain they consumed 5.63 lbs. of corn, 4.32 lbs. of hay, and 0.55 lb. of linseed meal. In the range-bred lots the 3-year-olds made an average daily gain of 2.72 lbs. and required 8 lbs. of corn, 4.34 lbs. of hay, and 0.70 lb. of linseed meal per pound of gain; the 2-year-olds averaged 2.55 lbs. gain daily and consumed 7.8 lbs. of corn, 3.57 lbs. of hay, and 0.78 lb. of linseed meal for each pound of gain; the yearlings made a daily gain of 2.52 lbs. and for each pound of gain required 6.6 lbs. of corn, 2.7 lbs. of hay, and 0.66 lb. of linseed meal. Deducting the gain made by one 2-year-old steer, which was considerably below the average, the 3-year-olds made an average gain for the whole period of 333
lks., the 2-year-olds 327 lbs., and the yearlings 318 lbs. There were 782 lbs. of pork produced following the 3-year-olds, 735 lbs. following the 2-year-olds, and 389 lbs. following the yearlings. Placing a value of 1 ct. a pound on concentrates and $8 a ton on hay, the average profit per head for the 3-year-olds was $16.46, for the 2-year-olds $12.85, and for the yearlings $13.20. This includes the pork produced but not the manure.

In shipping to market, a distance of 586 miles, the home-bred lots were fed sheaf oats and the range-bred lots prairie hay. The average losses per head for the lots fed sheaf oats were 3-year-olds 61 lbs., 2-year-olds 56 lbs., and yearlings 37 lbs.; for the lots fed prairie hay the average losses were 3-year-olds 53 lbs., 2-year-olds 49 lbs., and yearlings 30 lbs.

[Distillery slop for beef cattle] (Breeder's Gaz., 59 (1911), No. 24, p. 1412).—An account of the methods of feeding distillery slop as practiced in Kentucky, where about 50 per cent of the beef produced is made from distillery waste, although it is stated that the industry is diminishing because distillers obtain a better price for their slop when dried and shipped to Europe.

Cost of raising lambs, G. E. Day (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 36 (1910), pp. 135–137).—In an experiment with 30 lambs dropped from March 1 to March 5 the average weight at 2 months was 55.2 lbs. and the cost of gain 6.55 cts. per pound. This includes all food consumed by the ewes during the whole year, and service fees. less value of wool, but does not include risk, interest, and labor. The rations of ewes and lambs from lambing consisted of oats, bran, oil cake, roots, and alfalfa. Five of the lambs in the above experiment were kept on pasture with no supplementary feed until October 15, when they were put upon feed consisting of oats, oil cake, bran, hay, and roots for 30 days, at which time the 5 lambs weighed 664 lbs. and had cost 4.58 cts. per pound. The average daily gain for the 5 lambs before going to pasture was 0.71 lb., on pasture 0.37 lb., and in pen on full feed 0.47 lb.

Experiments with swine, G. E. Day (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 36 (1910), pp. 138–141).—The average cost per pig for raising 72 pigs to 11 weeks of age was $2.46. This includes service fees, maintenance of dry sows, and value of food consumed by sows and litters, but does not include risk, interest, labor, and manure.

Several experiments were conducted with 40 of these pigs to compare alfalfa, skim milk, and pasture, using corn meal as a check. In 90-day tests the meal alone produced an average daily gain per head of 1.07 lbs.; meal and alfalfa pasture, 1 lb.; meal and green alfalfa in pens, 1.13 lbs.; meal and skim milk in pens, 1.34 lbs.; meal, skim milk, and green alfalfa in pens, 1.36 lbs. In these tests 1 lb. of meal was equal to 4.3 lbs. green alfalfa or 6.79 lbs. skim milk. Valuing the pigs at $5 each, the skim milk at 20 cts. per 100 lbs., and the green alfalfa at $3 per ton, the price received per ton for meal with the hogs selling at 5 cts. per pound was $20.45, and at 8 cts. $53.

On the use of barley, barley feeds, and maize for fattening swine, H. Röck and D. Engberding (Fühlings Landw. Ztg., 59 (1910), No. 24, pp. 841–858).—Pigs about 7 months of age fed for a period of 49 days made an average daily gain per head of 0.711 kg. (1.56 lbs.) when maize and palm-nut cake were used as a supplement to potato flakes and skim milk, and 0.665 kg. when barley and an additional quantity of potato flakes were given as a supplement. There was but little difference in the percentage of dressed weight in the lots, or in the analytical constants of the fat, except that the melting point of the fat in the maize-fed lot was 2 per cent higher than that of the barley lot.

The development of the body of cattle from birth to the end of the growing period, W. Wagner ( Arb. Dcut. Gesell. Züchtungsk., 1910, No. 8, pp. 162, tables 15, pls. 14).—This contains data on the growth of cattle, determined
chiefly by periodical measurements. In general during the first year the greatest increase was in height, and the second year in length and breadth. In the third year there was some increase in breadth and a considerable increase in flesh.

There are many references to the literature on the subject.

Cattle in southern Rhodesia, R. Wallace (London, [1909], pp. 12, figs. 9).—A description of the characteristics of the native Africander cattle and crosses with European breeds.

Outlines of modern sheep breeding, U. Telschow (Grundriss der neuzeitlichen Schafzucht. Hanover, 1911, pp. 232, pl. 1, figs. 82).—This work treats of the anatomy and physiology of the sheep, the principles of breeding and feeding, and the common diseases of sheep. It is written from the natural history point of view, but so as to furnish information for the practical breeder.

Brood sows: Selection, feeding and management, C. Christopher (Arkansas Sta. Circ. 10, pp. 4).—This circular contains information for the practical swine breeder.

Contribution to the knowledge of breeds of swine in the German Colonies of the South Seas. M. Rauschke (Arch. Naturgesch., 77 (1911), I, No. 1, pp. 1-32, pls. 3).—A study of the origin and distribution of swine in the South Sea Islands.

From skeletal measurements the author concludes that Sus vittatus was the principal species of swine, S. niger and S. papuensis being only superficially different from the modern representatives of S. vittatus. On the Bismarck Archipelago and the Caroline Islands they are found mostly in a feral condition while in the Mariana Islands a larger number are domesticated. Some swine there seem to be a cross between S. vittatus and the wild S. scrofa, and one breed is apparently a cross between S. vittatus and Roman swine.

A bibliography is appended.

Lard from wild and domestic Philippine hogs and the changes in the constants produced by feeding copra cake, H. D. Gies and F. Agcoidi (Philippine Jour. Sci., A. Chem. and Geol. Sci., 5 (1910), No. 1, pp. 33-43).—Analytical constants are reported of lard obtained from the wild hog, native domestic hogs, and an imported Chinese breed.

"The variation in the constants of the lard of the Philippine wild hog from the normal lard values is seen to be rather slight and is chiefly noticeable in the low titer. The Koettstorfer number is slightly high. The iodin values, while about normal, are decidedly lower than the constants given by Lewkowitsch for the wild boar which was a native of the Temperate zone. . . .

From the results of this work it is evident that lean hogs will deposit a body fat with constants considerably influenced by coconut oil, when copra cake forms only a part of the ration. When the ration is composed almost entirely of copra cake the influence upon the constants is more remarkable."

The fat of animals fed on cottonseed meal, J. Sanarens (Ann. Falsif., 4 (1911), No. 28, pp. 72-75).—This is a statement of the results of a chemical and physical analysis of the butter, body fat, and lard obtained from animals fed cottonseed products. The results show that cottonseed oil was present in practically all the animal products.
The Devon pack horse as an army horse, C. R. Staveley (Jour. Roy. Agr. Soc. England, 71 (1910), pp. 79–90, pl. 1).—A brief account of the origin and history of the pack horse, with suggestions as to how the breed may be restored because of its value for artillery, transport, and cavalry service.

Horse breeding in Germany, G. Rau (Die deutschen Pferdezucht. Stuttgart, 1911, pp. IX+89, pls. 26).—A general account of the industry in Germany, and a study of noted individuals, with tables showing their ancestry.

Sex-limited inheritance and sexual dimorphism in poultry, H. D. Goodale (Science, u. ser., 33 (1911), No. 859, pp. 939, 940).—An experiment in crossing brown Leghorns with buff Plymouth Rocks is reported, in which it appears that a recessive character sex limited in inheritance can be utilized in an explanation of the mode of inheritance of sexual dimorphism.

Interim report on the poultry industry in Germany, E. Brown (Jour. Nat. Poultry Organ. Soc., 5 (1911), No. 1, pp. 6–33).—A statistical article, with special reference to the influence of the poultry industry in Germany on the supply of poultry products of the British markets.

Poultry experiments and management, T. I. Mairs and H. W. Jackson (Pennsylvania Sta. Bul. 107, pp. 3–14, figs. 3).—This contains information on hatching and raising chicks and on chick diseases, and reports feeding experiments.

The gains during the first 6 weeks with 4 different lots of chicks were as follows: A lot of 50 White Leghorns fed wet mash 3 times a day, in a yard which had been plowed and sown to oats and Dwarf Essex rape, made a gain of 42 lbs., and required 4.26 lbs. of feed to make a pound of growth in live weight. Sixteen Barred Rocks and 24 Rhode Island Reds fed a dry mash from a hopper, in a yard similar to the previous lot, made a gain of 50.75 lbs., and required 3.39 lbs. of feed for 1 lb. of gain. Fifty White Leghorns on a dry mash made a gain of 30.5 lbs., and required 4.54 lbs. of feed to make a pound of gain. Fifty White Leghorns fed a dry mash from a hopper, in a yard of sod composed of timothy, white and red clover, with some plantain and shepherd’s purse, made a gain of 33.5 lbs., and required 4.25 lbs. for each pound of gain. As the chickens grew older less feed was required, which was probably due to the fact that there was a great amount of forage furnished by the yards, incident to the ripening of the oats.

Three lots of chicks were used for a crate-fattening experiment. A lot of 16 Grade Barred Rocks, thin in flesh, made a gain of 10.75 lbs. in 3 weeks, while in the same time 1 Barred Rock, 2 Rhode Island Reds, 4 White Wyandottes, and 9 White Leghorns made a gain of 8 lbs., and a lot of 24 White Leghorns and 1 Black Minorca gained 13 lbs. in live weight. “The gain in weight is but a small part of the benefit of crate fattening. The most important benefit is the improvement in the quality of the flesh, which unfortunately can not be directly expressed in figures.”

The average cost per dozen of eggs from 138 pullets from October 1 to March 1 was 18.62 cts.; from March 1 to September 1, 5.48 cts. The average number of eggs per hen was 129.2. Valuing eggs at 3 cents each the average profit
per hen over and above the cost of food, which was charged at market price, was 76.5 cts.

In a pen of fowls which received their animal food in the form of butter-milk, 55 per cent of the eggs hatched; where 10 per cent of the dry mash was beef scrap, 50.5 per cent hatched; where the hens had all the beef scrap they wanted in a hopper, 33 per cent hatched; where no animal food was given, 59.5 per cent hatched; where hens received about three-fourths lb. green cut bone daily, 40.5 per cent hatched. In a pen of 23 Barred Rock pullets, the best and strongest of a lot of 46, mated to 2 males, full brothers, bred from a hen the eggs of which had hatched well, 93.6 per cent of the eggs were fertile and 73.4 per cent hatched. In the pen consisting of the remaining 23 pullets of the above lot, mated to 2 cockerels bred from a hen the eggs of which had hatched rather poorly and the chicks had had a mortality of 40 per cent, 97 per cent of the eggs were fertile but only 39.7 per cent hatched.

Farm poultry, with the results of some experiments in poultry houses and fattening chickens, W. R. Graham (Ontario Dept. Agr. Bul. 189, 1911, pp. 64, figs. 46).—This bulletin is intended to give information to farmers and others on general matters pertaining to the keeping of poultry. The subjects treated are the construction of poultry houses, egg production, feeds and feeding, incubation, rearing chickens, breeding fowls for market, for meat production, and for egg production, fattening chickens, dressing and shipping poultry, eggs for market, and breeds of poultry. The experimental data reported have been noted from other sources.

The effect of the present method of handling eggs on the industry and the product, M. E. Pennington and H. C. Pierce (U. S. Dept. Agr. Yearbook 1910, pp. 461-76, pl. 1).—This contains statistics on the production, storage, and consumption of eggs, with suggestions for improving methods of grading, packing, and shipping. It is pointed out that there is a great loss due to delays in marketing and bad methods of handling.

Data gathered from 20 shippers, from June to November, inclusive, showed that 4.36 per cent of the eggs received during that time were a total loss. There was a further partial loss for stale eggs, dirty eggs, and from other sources. Inquiry among country storekeepers in October showed that only about 25 per cent of the eggs of that month would rank as "firsts" on the Chicago market, 60 per cent as "seconds," due to long holding, 5 per cent cracked, and 4 per cent were rotten or stuck to the shells from long holding.

The sham Indian Runner duck (Farm Poultry. 22 (1911), No. 7, p. 203).—A note in support of the contention that the Indian Runner duck did not originate in India, but is a common breed in Holland, Belgium, and northern France, and native to that region.

The value of the shellfish industry and the protection of oysters from sewage contamination, G. W. Stiles, Jr. (U. S. Dept. Agr. Yearbook 1910, pp. 371-378, pls. 2).—This contains statistics of the industry of growing and canning oysters. Other topics treated are methods of growing oysters, enemies of the oyster, and the pollution of oyster beds by means of sewage. See also a previous note (E. S. R., 25, p. 161).

DAIRY FARMING—DAIRYING.

[Report of] the professor of dairy husbandry, H. H. Dean (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 36 (1910), pp. 106-131).—Little variation was found in the fat and lactometer determinations of samples of milk taken from the top and bottom of weigh cans at intervals of from 2 minutes up to 10 or 12 minutes after dumping,
In pasteurizing cream containing an acidity of between 0.2 and 0.3 per cent an albuminous coating formed on the inside of the pasteurizer, causing considerable trouble and delay. This trouble was not noticed in cream containing over 0.3 per cent acidity, nor in cream that was separated at the factory and then pasteurized. No reason is assigned.

In similar lots of cream pasteurized on the day of delivery with an acidity of 0.335 per cent and the following day at an acidity of 0.535 per cent, there was practically no difference so far as pasteurizing, churning, or loss of fat was concerned. The flavor of the butter was apparently injured by holding the cream so long before pasteurizing and churning, but the other qualities in the butter—grain and texture, color and salting—were not affected.

In experiments to test the effect of a culture on similar cream, raw and pasteurized, the lots pasteurized, whether with or without culture, churned in less time and made better quality butter than did the raw cream lots. "In these experiments there was little difference in the fat lost in the buttermilk by churning raw cream or pasteurized lots."

Continuing the tests of the different breeds, incomplete records for the year show the average percentage of casein by breeds was Holstein 2.2, Ayrshire 2.48, and Jersey 2.55, and that of fat was Holstein 3.44, Ayrshire 3.97, and Jersey 4.49.

The average moisture content of 21 samples of curd from western Ontario cheese series was 42.306 per cent; in 22 samples of green cheese, 34.664 per cent; in 11 samples of ripe cheese 34.638 per cent. The corresponding percentages of moisture in curd and cheese made at the college in 1910 were 49.282, 35.659, and 35.09.

A study of the effect of stirring curds at the time of dipping showed a tendency toward the development of more acid in the lots stirred. The moisture content was greater in the lots not stirred by 4.4 per cent in curds, 0.2 per cent in green cheese, and 0.48 per cent in ripe cheese. The average yield of cheese per 1,000 lbs. milk from the lots not stirred was 92.95 lbs., from the lots stirred, 92.06 lbs. The percentage of shrinkage during one month was 2.70 for the lots not stirred; for the lots stirred, 2.67. "The quality of the cheese was a little over one point better from the curds stirred." The conclusion is drawn that a medium amount of stirring of the curds at time of dipping will prove beneficial. However, as a result of 32 experiments along the same line, the conclusion is drawn that there is no advantage in giving the curds as much stirring at time of dipping as is the common practice.

In the work on relation of casein and fat in milk to the yield of cheese by months the highest percentages of fat and casein were in August, September, and October, due probably to advanced lactation in the cows. Many factors enter into the question of cheese making, such as skill of the cheese maker, losses of fat and casein in whey and during the process of making the cheese, amount of moisture left in the curd and cheese, length of time during which cheese is kept before selling, conditions of temperature, moisture, etc., in the ripening room, but on the average we shall not arrive at a more satisfactory basis of settlement with patrons than the fat-casein method. Milk containing an average of 3.862 per cent of fat and 2.652 per cent of casein produced 4.61 lbs. more cheese per 1,000 lbs. than milk containing an average of 3.527 per cent of fat and 2.442 per cent of casein. The quality of cheese from the low-casein milk was slightly better than that from the high-casein milk.

The yield of cheese was slightly greater and the quality better using a coarse than with a fine curd knife due probably, it is stated, to the higher moisture content of the green and ripened cheese by using the coarse knife.
Normal milk produced an average of 2.58 lbs. more of higher moisture content and better quality cheese than similar milk (but with slightly higher percentages of fat and casein), overripe. The yield of cheese was 0.753 lb. per 1,000 lbs. milk more when the curds were dipped with an acidity of 0.17 per cent than with the lots dipped at 0.2 per cent acidity. The quality of cheese was practically the same in both instances.

The effect of acidity at the time of adding the rennet (setting) was tested in a series of experiments. While the results were not so pronounced as expected, it was found that the loss of fat in the whey was slightly less, the yield of cheese greater by a little over 1 lb. per 1,000 lbs. milk, and the quality of cheese slightly better in the normal lots than in the high-acid lots.

There was practically no difference noted in the use of 2 brands of rennet extract having an acidity of 0.8 per cent and 1.22 per cent, respectively.

The dairy herd, G. E. Day (Ann. Rpt. Ontario Agr. Col. and Ext. Farm, 36 (1910), pp. 133, 134). — The record of the dairy herd for the past year is given. The averages for the herd of 31 cows are: Number of days milking, 276; pounds milk, 7,411; pounds fat, 274.65; cost of feed, $42.47; and profit, $26.19.

The dairy industry in the Netherlands, J. J. L. Van Ryn (Dairy, 23 (1911), No. 270, pp. 154, 155). — An abstract of a lecture before the British Dairymen's Association at The Hague, May, 1911. It gives a general and statistical account of the dairy industry of Holland, with special reference to the assistance rendered by the government and cooperative creameries.

Experiments in feeding diastasolin to calves, W. Müller and G. von Wendt (Fühling's Landw. Ztg., 60 (1911), No. 2, pp. 41-46). — Data are reported on feeding diastasolin. The average cost per kilogram of gain with 15 calves was 1.404 marks (about 15.2 cts. per pound).

Why do cream tests vary? Factors affecting richness of cream.—Relation of butter fat to butter, O. F. Hunziker (Indiana Sta. Bul. 150, pp. 27-55, figs. 15). — A series of experiments undertaken in order to demonstrate to the dairy farmer and creamery patron the effect of the different factors which cause variation in cream tests is reported.

In testing the effect of the richness of milk on the richness of cream, it was found that "all other conditions being the same 3 per cent milk produces 20 per cent cream, 4.5 per cent milk produces 30 per cent cream, and 6 per cent milk produces 40 per cent cream." Three series of experiments were carried out to illustrate the results of the rate of inflow, by which it was shown that
the percentage of cream could be varied from 23.5 to 71.5. By varying the speed of the separator the percentage of cream was made to vary from 10 to 65.5. In studying the effect of temperature on the richness of cream, the average result at a temperature of 90 to 95° F. was 21.2 per cent fat, and at 50 to 60° 31.7 per cent. When the cream was separated at 50° the separator was sometimes clogged, causing the fat in the cream to run as low as 12 per cent.

Experiments were conducted to definitely show the effect on the richness of cream of the amount of water used to flush the bowl with the following results: When no water was used the average percentage of fat in the cream was 37.8; with water equal in amount to the capacity of the bowl, 37.3; with sufficient water to cause the cream discharged to appear watery, 35, and when twice the amount of water needed to produce a watery cream discharge was used the percentage of fat in the cream was 33.5 per cent.

Directions are given for calculating the amount of butter when the cream test is known and other matters relating to the separation and care of cream are discussed.

The grading of cream, B. D. White (U. S. Dept. Agr. Yearbook 1910, pp. 275–280).—The author points out that much poor cream is received at the creameries because there is no incentive for the farmer to deliver good cream. The data obtained from creameries in Minnesota, Wisconsin, and Iowa show that the difference in price paid to patrons by the creameries is 2.07 cts. per pound of butter fat in favor of the creameries receiving sweet cream or whole milk. Besides paying on the basis of the quality of cream, a number of other suggestions are offered for improving the quality and grading the cream.

Cream cooling on the farm, M. Comans (Jour. Dept. Agr. Victoria, 9 (1911), No. 5, pp. 312, 313, fig. 1).—A cooler and aerator, which was found to reduce the temperature of cream 22° as it came from the hand separator, is illustrated and described. It is thought that its use should improve the quality of the cream delivered to the milk factory.

Churnability of cream, W. F. Cooper (Jour. Roy. Agr. Soc. London, 71 (1910), pp. 113–122, figs. 6).—This is a preliminary report on the factors which affect the churnability of cream, which contains data on the number and size of globules of milk from different breeds. An apparatus for churning different creams simultaneously and for recording the length and number of strokes while churning is illustrated and described.

Investigations on the consistency of butter and butter fat, Hesse (Molk. Ztg. [Hildesheim], 25 (1911), No. 42, pp. 788–790).—A study of the factors which affect the texture of butter led to the conclusion that the chief factor was the nature of the fat in the ration, although the temperature at churning and the length of churning and working are of some effect.

The "Kingston" cheese; a cheese for small-holders and others, A. Todd and W. Sadler (Jour. Bd. Agr. [London], 18 (1911), No. 3, pp. 193–203, fig. 1).—A description is given of the method of making a new variety of cheese, weighing from 1 to 2 lbs. and fit for consumption 10 days after making, yet retaining the qualities of hard pressed cheeses of large size.

Studies on the bacterial flora of cheese, C. Gorini (Atti R. Accad. Lincei. Rend. Cl. Sci. Fis., Mat. c Nat., 5. ser., 19 (1910), II, No. 3, pp. 150–158, fig. 1; abs. in Centbl. Bakt. [etc.], 2. Abt., 29 (1911), No. 9–11, p. 229).—In a study of cheese ripening the author finds that a liquefaction of gelatin is not a good criterion for determining whether or not a species of bacteria has proteolytic properties. He accordingly divides the proteolytic micrococci into two groups, Micrococcus casei proteolyticus I, which liquefies gelatin, and M. casei proteolyticus II, which does not liquefy gelatin. The importance of studying the power of these species to attack casein in an acid medium is pointed out.
Losses in making cheese from overripe milk, R. Harcourt (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 36 (1910), pp. 98, 99).—In commenting on the value and cheapness of milk as a food attention is called to the large percentage of its value lost in making butter and cheese. In making butter very little but the fat of the milk is used; all the protein, sugar, and ash remains, and under present conditions usually goes back to the farm as feed for stock. In making cheese nearly half of the solids are lost in the whey, which, because of the ease with which it ferments, is only partly recovered as a hog feed. "If these milk solids could be put up in a solid form cheaply without decreasing their digestibility or flavor, a very valuable food would be added to those now available for human consumption."

The process of manufacture of a commercial casein product from whey by the use of sulphuric acid is described, and comments are made on the advisability of feeding hogs the whey residue on account of its free sulphuric acid content. It is stated that the acid condition can be easily overcome by the addition of lime, forming the harmless calcium sulphate. Feeding experiments are needed to ascertain the effect of the whey on hogs. Samples analyzed contained about 0.25 per cent fat and from 0.35 to 0.40 per cent protein.

Buttermilk cheese making at the creamery, J. L. SAmMIs (Wisconsin Sta. Bul. 211, pp. 3–17, figs. 7).—This is a more extended description of the preparation, packing and marketing, and food value of buttermilk cheese, previously noted (E. S. R., 23, p. 181).

The product may be shipped in butter tubs and retailed in paper pails or other small packages. It will keep for a week or 10 days at 50 or 60° F., but can be kept longer if stored at 32° or lower. Buttermilk from rich cream containing more than 50 per cent fat, or from cream which was pasteurized when very sour, is not suitable for making buttermilk cheese. "Buttermilk cheese has about the same food value, pound for pound, as lean beefsteak, which sells at twice the price." Improved methods of draining the curd in large quantities are described in detail, and directions are given for the construction and use of a draining rack for large creameries and of a floating strainer and siphon.

VETERINARY MEDICINE.

Antistreptococcc serum therapy in bovine pathology, L. Paris (Rec. Méd. Vét., 88 (1911), No. 7, pp. 238–240).—The author here details the very favorable results obtained with antistreptococcc serum for calves and foals and compares them with those obtained with other therapeutie measures.

The influence of subcutaneous injections of serum upon the opsonic index, O. Hartoch and N. SiRENskij (Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 8 (1911), No. 5–6, pp. 602–610).—The subcutaneous injection of a normal non-
specific serum into a guinea pig increases the phagocytic stimulating power of the guinea-pig serum. This is a specific stimulation.

In regard to the pathogenic action of the intracellular toxins of the Micrococcus melitensis, V. Cavacini (Ann. Ig. Sper., n. ser., 20 (1910), No. 2, pp. 179-197, pl. 1; abs. in Ztschr. Immunitätsf. u. Exptl. Ther., II, Ref., 3 (1910), No. 12, pp. 1038, 1039).—The author injected intraperitoneally, killed bouillon and agar cultures of M. melitensis, ascitic fluid, and goat serum into rabbits. The bouillon cultures, goat serum, and ascitic fluid had only a transitory effect on the animal organism and were never lethal, while the agar cultures produced acute and chronic forms of the disease and often resulted in death after a short time. By giving small doses of the killed bacilli from agar cultures, agglutinins and specific deviating substances were found in the blood. The serum in vitro was also bacteriolytic.

It was also possible to immunize rabbits in this way, but the serum obtained from such animals did not protect nonimmune animals.

Weber's reaction and Trichocephalus, J. Guial and C. Garin (Searsine Med. [Paris], 29 (1909), No. 35, pp. 411, 415; abs. in Jour. Amer. Med. Assoc., 53 (1909), No. 14, p. 1139).—The authors have found the Weber reaction or guaiac blood test to be positive in 13 cases in which the eggs of Trichocephalus were found in the stools, and eggs were never found without this positive reaction occurring sooner or later.

Report in regard to the activities of the division of animal hygiene of the Emperor Wilhelm Institute for Agriculture at Bromberg, Miessner (Mitt. Kaiser Wilhelm's Inst. Landw. Bromberg, 5 (1910), No. 1, pp. 30-34; abs. in Ztschr. Immunitätsf. u. Exptl. Ther., II, Ref., 3 (1910), No. 12, p. 1033).—This is a short, scientific, and practical report of the work done during the fiscal years 1906 to 1909 in regard to the serodiagnosis of glanders, Tauruman and bovovaccination, aggressin test, and chemotherapeutic test for hemoglobinuria in bovines, etc.

The results of these tests are to be reported in some later scientific publication.

Annual report of the veterinary pathologist for the year 1909-10, R. E. Montgomery (Dcpt. Agr. Brit. East Africa Ann. Rpt. 1909-10, pp. 55-88).—This report on the work of the year includes appendixes devoted to (1) the details of routine examinations at the laboratory, (2) East Coast fever, (3) coccidiosis, and (4) rinderpest.

Anthrax, C. F. Dawson (Delware Sta. Bul. 90, pp. 3-61).—A report of investigations in cooperation with the Bureau of Animal Industry of this Department.

After giving a brief account of the history of anthrax, variously known as splenic fever, malignant pustule, woolsorters' disease, charbon, and milzbrand, the author discusses the biology of the causative organism, the channels of infection, infection of the soil, the various forms and symptoms of the disease, anthrax in swine, birds, and man, microscopic diagnosis, post-mortem appearances, disposition of carcasses, susceptibility, and vaccination against the disease.
Under the last head, which includes a consideration of the several methods and vaccines thus far proposed for producing immunity, the author summarizes particularly his experience with the Pasteur method, the principal drawback to which seems to be the length of time required, which in the event of an outbreak is a serious disadvantage. With the idea of finding a method whereby an immediate immunity could be established in existing outbreaks, or whereby immunity could be produced under ordinary conditions in a shorter time than with the Pasteur treatment, the author conducted some experiments as a result of which he announces that he has produced an antibacterial serum by highly immunizing sheep by repeated inoculations, first of attenuated anthrax bacilli, and following these by inoculations of the most virulent races of the bacilli in increasing doses until the animal would withstand fifty thousand times the minimal lethal dose, with impunity. Such a serum will protect a sheep against an otherwise mortal dose of bacilli and produce an immediate immunity. . . .

The serum will confer a passive immunity immediately, and thus protect the animal against fatal infection over the period which is necessary for the vaccine to confer an active immunity. Where an animal which has been protected by the serum becomes infected with an otherwise fatal bacillus, the results of this infection will be the production of a much stronger immunity than the vaccine and serum would confer.

Pyocyanase made after the method of Emmerich and Loew gave some good results when tested upon rabbits, but failed upon sheep. Anthraxin, which is made in a manner similar to mallein and tuberculin, was tested in regard to its efficacy with the result that it was not found to possess any immunizing properties. Some tests were also made with a commercial vaccine in pill form, but immunity could not be obtained with it.

"Anthraxase, prepared by the writer after the same general method used in producing pyocyanase, was without protective or curative properties, although it produced high fever when injected into rabbits and sheep subcutaneously."

Anthraxin, consisting of a turbid suspension in carbolized normal salt solution of dead sporeless anthrax bacilli, was apparently useless in protecting sheep against anthrax when used similarly to the Pasteur vaccine.

A single vaccine, which had for its object the production of immunity in 2 weeks and thus cutting down the necessary period by 2 weeks, was made by the author by incubating a virulent bacillus for about 18 days at 42 to 43° C. "Such a culture, which will kill guinea pigs in about a week, thus holds a position between the two vaccines of Pasteur in strength. With it sheep were vaccinated and after 12 days withstood an otherwise fatal infection with virulent bacilli. That the immunity was not in all cases sufficiently strong was evidenced by the death now and then of a sheep when tested with virulent bacilli."

Along with the above investigations for studying the biology of the causative organism and the general sanitary aspects of the subject, it was decided to test the efficacy of freshly-prepared Pasteur vaccines, as it was believed that some of the bad results that have been reported as following the use of Pasteur vaccine were due to carelessness on the part of those preparing and using it. Vaccines 1 and 2, prepared by the author, were therefore submitted to practicing veterinarians of the State of Delaware to be used on receipt, the vaccine No. 2, however, not being shipped until 12 days after vaccine No. 1. The results of observations for 2 years indicated that the use of fresh vaccines from bacteria which had been incubated for from 4 to 5 days or until the bacteria sporulated is a good procedure to follow. The author believes that vaccine so prepared will remain active for several months.
The author "does not advise the abandonment of the old Pasteur system of vaccination against anthrax when it is practiced upon animals before they are turned out on the pastures in the spring of the year. When animals are dying, however, vaccination alone requires too long a period to protect, and it is in these outbreaks that the antiantarax serum should be used in conjunction with vaccine. The experiments have shown that a single vaccine may be used with good results. Where it is desired, however, the serum may be used simultaneously with the double vaccine of Pasteur."

Comparative investigations of the value of the various biological methods for diagnosing glanders, M. Müller, W. Gaetgens, and K. Aoki (Ztschr. Immunitätsf. u. ExpL Ther., I, Orig., 8 (1911), No. 5-6, pp. 626-664; pl. 1, dgms. 7).--The methods tested were the ophthalmic, cutaneous (mallein reactions), agglutination, precipitation, complement fixation, and the opsonic index with normal animals and animals infected per os.

According to the authors there is no single method which will with certainty detect glanders in all stages of the disease, but the best and most certain methods for nonclinical or occult cases are the malleinization of the skin and conjunctiva and the complement fixation test. The author prefers a combination of the 3 and their repeated use.

The opsonic index is considered of no value for veterinary police purposes.

Malta fever in domestic animals, C. Dubois (Recr. Vet. [Toulouse], 36 (1911), Nos. 3, pp. 120-110; 4, pp. 199-212; 5, pp. 269-281).--The first paper deals with the history, bacteriology, epidemiology, symptoms, and lesions; the second with the diagnosis, prognosis, etiology, and pathogeny; and the third with the treatment of this affection in domestic animals, its transmission to man, and prophylaxis.

Some observations on the transmission of Piroplasma bigeminum by ticks, A. Theiler (Bul. Soc. Path. Exot., 2 (1909), No. 7, pp. 384, 385).--The larvae of Rhipicephalus decoloratus from females engorged on horses have been found to be capable of infecting cattle with P. bigeminum. It thus appears that this parasite can be hereditarily transmitted, not only from one generation of its tick host to another, but also to a third as has been shown to be the case with Spirocheta duttoni in Ornithodoros moubata.

Recurrent fever in Colombia, E. Robledo (Bul. Soc. Path. Exot., 2 (1909), No. 3, pp. 117-129).--The symptoms of the recurrent fever that occurs in Colombia are said to be similar to those of African tick fever. The parasite which resembles Spirocheta duttoni is transmitted by Ornithodoros chinche (Argas americana). This tick is said to be very abundant in the warm sections of Colombia, particularly in abandoned houses, on herbage, straw, etc., and attacks the traveler with great avidity.

Note on a cattle trypanosomiasis of Portuguese East Africa, W. Jowett (Jour. Compar. Path. and Thor., 23 (1910), No. 3, pp. 251-271, figs. 5).--In this paper the author gives an account of the general morphological features, together with some animal reactions, of the trypanosome found in the neighborhood of Beira during an expedition to Portuguese East Africa.
Further note on a cattle trypanosomiasis of Portuguese East Africa. W. Jowett (Jour. Comp. Path. and Ther., 24 (1911), No. 1, pp. 21-40, figs. 6).—In this paper the author gives a more complete list of animal reactions of the trypanosome, and reports upon the effect of passing the trypanosome through a series of rats, by transmission experiments, and the action of certain chemical agents on the trypanosome in vivo.

The results indicate that the trypanosome may be transmitted mechanically by one or other of the 2 genera of biting flies used in the experiment, namely Hematopota and Stomoxys.

The transmission of African horse sickness to the dog by feeding, L. E. W. Bevan (Vet. Jour., 67 (1911), No. 433, pp. 492-498, figs. 2).—The author here reports observations and experiments which led to the conclusion that dogs may become infected with African horse sickness in natural circumstances by feeding on infective meat.

Trypanblue in infectious anemia. A. W. Whitehouse (Amer. Jour. Vet. Med., 6 (1911), No. 8, pp. 686-688).—One of 3 cases of infectious anemia treated by the author with trypanblue recovered from the disease. In the case of the animal that recovered the treatment consisted of the administration of 3 grains of trypanblue dissolved in 200 cc. of sterilized cold water, the solution being raised to body temperature and injected at one application into the jugular vein.

Researches on trichinosis, M. Romanovitch (Compt. Rend. Soc. Biol. [Paris], 70 (1911) Nos. 8, pp. 257-259; 9, pp. 339-341; 16, pp. 378, 379).—This series of articles deals briefly with the experimental investigations of the action of Trichinella spiralis on the animal organism, its migration, and remedial measures. The investigations led the author to conclude that the fever, abscesses, and septicemia resulting in death as sometimes observed in human cases are due to the microbes inoculated by the trichine.

Experiments with the intradermal test for tuberculosis in cattle, A. R. Ward and G. S. Baker (Amer. Vet. Rev., 38 (1910), No. 2, pp. 184-193).—The authors summarize their work as follows:

"We have shown that 28 out of 30 reactions regarded by us as positive, proved positive on autopsy. Of 4 considered questionable 3 proved positive on slaughter. Two diagnosed as positive showed no lesions. Fifty-nine considered as nonreactors proved negative on autopsy. Seven classed as negative reactions showed lesions. The determination of a reaction calls for careful discriminating judgment on the part of the operator. With regard to the 7 cases of tuberculosis which we failed to recognize by the test, we prefer to attribute these to our inexperience rather than to a failure of the test. It is the only test so far known that is applicable to range cattle on the range. In comparing the subcutaneous and intradermal tests we find a remarkably close agreement in results. It requires no modification of the ordinary routine of the animals, except that in range cattle it is necessary to confine them while making the injection, and again 48 hours later to make the diagnosis. The time of this confinement is insignificant. The intradermal test applied 5 days after the subcutaneous test is not reliable."

The eradication of cattle tuberculosis in the District of Columbia, R. W. Hickman (U. S. Dept. Agr. Yearbook 1910, pp. 231-242).—This is a detailed account of the manner in which the work of eradication of cattle tuberculosis in the District of Columbia commenced November 29, 1910, was conducted, together with the findings and results obtained.

During the 4 months following that date 1,701 head were tested, of which 1,380 were apparently free from tuberculosis and 321 reacted and were slaughtered.

9204°—No. 6—11—7
In the post-mortem inspections of these carcasses, the correctness of the tuberculin reactions was verified in 98.36 per cent of the reactors, leaving only 1.64 per cent in which no tuberculous lesions were found. As an examination was not made of the deep-seated lymphatic glands and the interior of the joints, even this small percentage cannot be positively classed as errors in diagnosis."

"Promptly following the removal of reacting cattle, the premises that had been occupied by them were thoroughly cleaned and disinfected under the supervision of a Bureau employee, a solution of bichlorid of mercury in water, 1:500, being used for this purpose and applied in the form of a spray by means of a strong force pump."

The work of retesting after the lapse of 6 months was started June 1, taking in order those herds from which reactors had been removed and slaughtered. "Of the 75 premises originally infected . . ., the number upon which a second infection was found was 13. Therefore the work so far accomplished has resulted in eradicating tuberculosis from 62 centers of infection . . . More than one-half of the reactors on the retest were on 2 of the 13 premises. The percentage of premises showing a second infection is 17.33, and the percentage of reacting cattle on the retest is 4.47." At the time of writing (October 15, 1910) a second retest was under way.

The order of the Commissioners of the District for the suppression and prevention of tuberculosis in cattle, under which this work was conducted, is appended to the account.

Specific chronic enteritis of bovines; ophthalmic and cutaneous reaction with avian tuberculin, H. Horne (*Berl. Tierärzt. Wochenschr.*, 26 (1910), No. 5, pp. 109, 110, fig. 1).—A 14-day-old female calf was fed with the intestinal mucosa obtained from a cow affected with pseudotuberculosis of the intestinal tract. The feeding was repeated after 6 weeks with the mucus membrane from another animal. After the last feeding the calf remained apparently well, increased in weight, and was only affected a few times with diarrhea. Acid-fast bacilli could not be detected with any degree of certainty in the feces.

A year later the animal gave both an ophthalmic and cutaneous reaction with avian tuberculin, but not with tuberculins from other sources.

Lamziekte, W. Robertson (*Jour. Comp. Path. and Thr.*, 23 (1910), No. 3, pp. 229–239, *figs. 3*).—A detailed account of this disease. The author has isolated a bacillus which he thinks to be the causative organism of the disease. The use of the toxin obtained from a bouillon culture was of no value as a prophylactic agent. The author had some measure of success with cultures killed by heat, some 500 head of cattle being provisionally inoculated at the time of writing.

In regard to the quantitative determination of the antirenin content of milk by the rennet inhibition test, and also some remarks in regard to other hygienic milk tests, K. Schern (*Berl. Tierärzt. Wochenschr.*, 26 (1910), No. 5, pp. 123–129, *fig. 1*).—The author investigated the behavior of the catalase test with cow's milk, and determined that fresh milk from the same animal gave very different results on different days.

It is not believed that the findings with the catalase test can alone be relied upon for the diagnosis of mastitis. See also a previous note (E. S. R., 24, p. 213). The author also does not believe that the hemolytic method, as recommended by Bauer and Sassenhagen (E. S. R., 23, p. 114; 25, p. 200), will find
universal application on account of the difficult technique involved and, furthermore, the cost of conducting the test.

The author finally points out the value of the acidity test (E. S. R., 24, p. 125) as a preliminary test and of the autotrenmet test (E. S. R., 21, p. 707) for detecting milk from diseased animals.

The treatment of milk fever, V. VOGADI (Állatorvosoi Lapok, 32 (1909), No. 51, pp. 623, 624; abs. in Berlin, Tierärztl. Wechschr., 27 (1911), No. 9, p. 153).—A number of cases are described which occurred among those animals which were pastured the longest.

The author wishes to emphasize that the disease is not restricted to debilitated animals or animals which have been kept under unhygienic conditions, but that it primarily stands in a close relation to gestation and parturition rather than to the breed and external factors. The author often utilized Schmidt's method without success, and with it in some instances the condition became worse. Only after the udders were washed out with pure water (and in another case, when a subcutaneous injection of strychnin was given) did the animals improve.

In another case a lavage of the uterus followed by a rectal douche was performed with ultimate recovery. Milk fever can often be remedied without injecting the udder.

Report on experiments with the wild passion-flower vine in connection with the death of cattle in the Beaudesert District (Queensland), S. DOOD (Jour. Compar. Path. and Ther., 23 (1910), No. 3, pp. 205–212).—The author's experiments indicate that the white passion-flower vine (Passiflora alba), a native of Brazil, which has now become a naturalized weed in Queensland, was responsible for the illness and death among cattle near Beaudesert, where the investigations were made, and that it has been the cause of a great deal of sickness among the cattle of that district.

Combating calf dysentery and calf pneumonia, O. SCHREIBER (Berlin, Tierärztl. Wechschr., 26 (1910), No. 49, pp. 969–973; abs. in Ztschr. Immunitättsf. u. Expt. Ther., II, Ref., 3 (1910), No. 12, p. 1037).—Aside from the usual prophylactic measures, the author sees salvation only in vaccination. Good results can be obtained with the serum and bacterial extract methods, as is shown by the work of the author.

A new nematode parasite of the ox (Onchocerca gutturosa n. sp.), L. G. NEUMANN (Rev. Vet. [Toulouse], 35 (1910), No. 5, pp. 279–278, figs. 5; Jour. Trop. Vet. Sci., 6 (1911), No. 1, pp. 101–105, figs. 5).—Nearly all adult cattle slaughtered at the abattoir at Constantine are said to harbor this parasite. It has been found in animals brought from more than 200 kilometers from Constantine, and is thought to occur throughout northern Algeria and Tunisia. It especially affects the cervical ligament, chiefly at the internal surface of the layers in a more or less abundant connective tissue and particularly near the second and third dorsal vertebrae. It has occasionally been found in the intramuscular tissue of the thigh.

Gilruth's cyst in the gastric mucosa of bovines, E. CHATON (Arch. Zool. Exp. et Gén., 5, ser., Notes et Recr., 5 (1910), No. 4, pp. CXIV–CXXIV, figs. 7; abs. in Bul. Inst. Pasteur, 8 (1910), No. 18, pp. 783, 784).—This is a report of studies made of the protozoan parasite first discovered by Gilruth in Tasmania, a preliminary account of which has been previously noted (E. S. R., 23, p. 485). The name Gastrocyctis gilruthi is proposed for it.

In regard to vaccinating animals against hog cholera, P. UHLENHUTH (Berlin, Tierärztl. Wechschr., 27 (1911), No. 13, pp. 220–223).—A critical discussion in regard to Damman and Stedefeder's findings, accompanied by a few examples to refute some of the statements made. (E. S. R., 24, p. 390.)
Our horses, their diseases and treatment, G. S. Heatley (London, 1911, pp. XI+186).—This is a practical guide.

Pernicious anemia of horses, P. Schlathölter (Über die perniziöse Anämie der Pferde. Inaug. Diss., Univ. Bern, 1910, pp. 58, pls. 2; abs. in Centbl. Bakter. [etc.], I. Abt. Ref., 59 (1911), No. 5, pp. 133, 134).—According to the author, pernicious anemia is caused by an ultrafilterable virus which is present in the blood and urine of horses affected either actively or latently. If either the urine or blood from infected animals is given per month (or on hay or straw), or is injected into the blood stream of normal animals, the disease is conveyed to these animals. Other domestic animals do not take the disease. The incubation period after artificial infection is as high as 3 months. Natural infection seems to have a still longer incubation period.

No effective treatment was found, but the author advises thorough prophylaxis.

Vaccination against equine influenza, Vaeth (Berlin. TierärztL. Wehnschr., 26 (1910), No. 5, pp. 110, 111).—As a result of the author's work with numerous cases of this disease he believes the Gans serum to possess a protective action.

Toxic substances from Ascaris megaloecephala.—Experimental investigations with the horse, M. Weinberg and A. Julien (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 3, pp. 337–339; abs. in Rec. Yct. [Toulouse], 36 (1911), No. 5, pp. 257, 258).—In the investigations here reported 39 horses were used. A clear sterile peritoneal liquid obtained from A. megaloecephala was instilled into the left eye of 34 horses and injected into the nasal cavity of the other 5.

The reactions obtained demonstrate that this ascarcid secretes substances toxic to the horse. As none of the 16 horses which reacted were carriers of ascarids, and since 8 horses that were infected were found to be immune to the toxic action of the instilled liquid, the authors think that the horse becomes immune to the toxic substances secreted by this parasite.

In regard to fibrosin, Spaeth (Berlin. TierärztL. Wehnschr., 27 (1911), No. 9, pp. 148, 149).—Fibrolisin did not show any curative or other effect with either a subcutaneous phlegmon or elephantiasis on the extremities of horses.

Elephants and their diseases, G. H. Evans (Rangoon, 1910, pp. XIV+313, pls. 28, figs. 36).—This treatise on elephants is divided into 5 parts and 9 appendices. Part 1 consists of a general account; part 2 is entitled Outlines of Anatomy and Physiology; part 3, Medicines and their Administration—Formule; part 4, Noninfective Diseases; and part 5, Infective Diseases.

The appendices are devoted, respectively, to law cases, operations, age, growth increment, list of fodder plants, grasses, etc., eaten by elephants, breeding, case of impaction and rupture of the esophagus, surra, and a note on infectious diseases with special reference to anthrax.

Bacillary white diarrhea of young chicks, L. F. Rettger and F. H. Stoneburn (Connecticut Storrs Sta., Bul. 68, pp. 279–301, table 1, figs. 5).—This is a report of studies conducted in 1910 in order to corroborate those previously reported (E. S. R., 22, p. 489). The information presented includes accounts of infection by the food supply, of the mother hen as the original source of infection, the presence of Bacterium pullorum in the yolks of fresh eggs, methods and results of testing fresh eggs, bacteriological examination of eggs incubated for varying lengths of time, symptoms and post-mortem appearances of the disease, and additional points of interest and practical suggestions.

The following is a summary of the information presented: "The original source of infection is the ovary of the mother hen. Eggs from infected hens contain the organism in the yolks. Chicks produced from infected eggs have the disease when hatched. The disease may be spread through the medium of infected food and water, hence normal chicks may acquire it by picking up
infected droppings or food contaminated thereby. Infection from chick to chick can not, apparently, take place after they are three or four days of age. As a rule, infected chicks make less satisfactory growth than those that are apparently normal, and for some time they appear stunted and weak, but may eventually undergo more or less complete development. The female chicks which survive often harbor the infecton and may become bacillus carriers, infection in the breeding pens being perpetuated in this manner. In all probability infection does not pass from adult to adult. Infected hens are apparently poor layers, especially in their second and subsequent laying season.

A therapeutic agent for fowl diphtheria, J. Reidenbach (Leipzig, Geflügel Ztg., 1910, No. 11; abs. in Berlin. Tierärztl. Wochenschr., 26 (1910), No. 5, p. 116).—After trying numerous antiseptics against fowl diphtheria, among the number being 50 essential oils, the author concludes that ajowan oil possesses the strongest antiseptic action and is better than carbolic acid, formic acid, and formaldehyde. This oil is obtained from the fruit of *Psychotis capitica*, an annual plant which resembles caraway and has for its habitat Egypt, Persia, and the East Indies.

Spirillosis of fowls and *Argas persicus* in Roumania, D. Mæzincescu and J. Calinescu (Bul. Soc. Path. Exot., 2 (1909), No. 6, pp. 292, 293).—The authors have found fowl spirochelosis to occur in Roumania, and think that in that country it is the cause of a large part of the mortality among domestic fowls which has been reported to be due to fowl cholera.

Ducks and geese, as well as the common fowl and occasionally young turkeys, are attacked by the disease. *Argas persicus* has been found to be abundant in all poultry houses in which the disease has been observed to occur. The authors report a high mortality in naturally infected fowls but much lower in those artificially infected.

The filaria in the turkey's eye, M. Ozoux (Compt. Rend. Soc. Biol. [Paris], 68 (1910), No. 29, pp. 974, 975).—The author reports that a filaria, probably *Oxy spirura mansoni*, frequently occurs beneath the membrane nictitans of turkeys in all parts of the island of Réunion, as many as 8 having been found in one eye. None could be found in the blood.

A trematode parasite of the English sparrow in the United States, L. J. Cole (Bul. Wis. Nat. Hist. Soc., n. ser., 9 (1911), No. 1-2, pp. 42-48, pls. 2; abs. in Science, n. ser., 33 (1911); No. 857, p. 853).—The author has found young English sparrows at Madison, Wts., to be very commonly infected with the trematode parasite *Monostoma faba*. This parasite, which forms conspicuous cysts in the skin of the abdominal region, has long been known in Europe but has hitherto been reported in only 1 or 2 isolated cases on this continent. In the locality of Madison it appears to cause a certain mortality and it is thought possible that it may become one of the means which will help check the increase of the English sparrow. Unfortunately it attacks other small passerine birds of several families as well.

A bibliography of 7 titles is appended.

On a Halteridium and Leucocytozoon of the wood owl and their further development in mosquitoes, M. Mayer (Arch. Protistenk., 21 (1911), No. 3, pp. 232-254, pls. 2).—The author has found a Halteridium in the wood owl (*Syrinium aluco*), which develops in Culicidae to flagellates (in *Culex annulatus* at room temperature and in *C. pipicous* and *Stegomyia calopus* at a lower temperature) for which the name *H. syrnia* is proposed.

"Beside a Leucocytozoon of the wood owl motile forms were found in the blood analogous to those described by Schaudinn; these have hitherto been observed only in association with it and certainly belong to its cycle. A partial
further development of the Leucocytozoon in Schaudinn's sense was observed in C. pipiens and S. calopus, that is, the formation of large ookinetes and later of large slim flagellates which progressed like spirochetes. Schaudinn's work on alternation of generation and host in trypanosome and spirochete infection could thus in important points be confirmed."

**RURAL ENGINEERING.**

Progress and present status of the good roads movement in the United States, L. W. Page (U. S. Dept. Agr. Yearbook 1910, pp. 265–274).—This article briefly summarizes the history of road development in this country, and discusses the outlook for the future.

"The present trend of road affairs throughout the various States is toward a reform in administration and the adoption of a more progressive policy. The old system of paying road taxes in labor has proved inefficient and is being rapidly discarded for the better plan of requiring all road taxes to be paid in cash. It is also apparent that the State will ultimately be the unit of administration and will largely control and direct road work in the counties and townships. A reduction in the number of road officials is also inevitable, and knowledge and skill in road building will be required of each official."

Special road problems in the Southern States, D. H. Winslow (U. S. Dept. Agr., Office Pub. Roads Circ. 95, pp. 15, figs. 13).—This circular discusses a number of road problems encountered in the Southern States and suggests comparatively simple and inexpensive remedies available by the use of local materials and labor. These include methods of draining a flooded road by raising one side with logs, stones, or similar material; the construction of roadbeds, with a V-shaped foundation filled with rocks, brickbats, or sand to serve as a drain in swamp sections and low levels; and the protection from erosion of roads and ditches by the use of planks or trenches filled with logs.

Progress reports of experiments in dust prevention and road preservation, 1910 (U. S. Dept. Agr., Office Pub. Roads Circ. 94, pp. 56).—Experiments conducted during the summer of 1910 are reported, together with supplementary observations on experiments previously noted (E. S. R., 23, p. 489).

In the tests at Ithaca, N. Y., in cooperation with Cornell University for the purpose of ascertaining the relative value of different road binders under various conditions, their average total cost per sq. yd. was as follows: Penetration method, oil-asphalt 70.1 cts., refined asphaltic preparation 75.34 and 63.4 cts.; prepared-filler method, oil-asphalt $3.69 and 92.34 cts.; and mixing method, oil-asphalt $1.14 and $1.03, refined semiasphaltic oil $1.05 and 98 cts., and refined water-gas tar 93.37 and 90.87 cts.

Tests with tar and oil preparations at Knoxville, Tenn., showed a total cost per sq. yd. of 60.04 cts. for refined coal tar, 53.98 cts. for refined tar preparation, and 53.71 cts. for oil-asphalt. All the treatments appeared satisfactory when last inspected.

A 300-ft. section at Ames, Iowa, was surfaced with gravel and oil-asphalt at a total cost of 17.782 cts. per sq. yd. An oil-gravel-macadam treatment at Bolse, Idaho, cost a total of 28.83 cts. per sq. yd.

In a continuation of the trials at Washington, D. C., concentrated waste sulphite liquor and semiasphaltic oil emulsion were used at costs ranging from 3.26 to 14.83 cts. per sq. yd. Somewhat better results were obtained from the materials when used alone, as the emulsion would, to a considerable extent, waterproof the road surface and prevent proper absorption of the sulphite liquor in later treatments. Treatments with oil-cement-concrete ranged in cost from $1.15 to $1.26 per sq. yd. with fluid residual petroleum, and from $1.12 to
$1.26 with cut-back petroleum residue. When no oil was used the cost was
$1.13. At the time of the last inspection all sections were in excellent condi-
tion with no important differences apparent between them.

Oil-cement-concrete applications in New York City cost 89.53 cts. and 85.28
cts per sq. yd. using fluid residual petroleum, and $1.02 using cut-back petro-
leum residue, but the results are reported as being apparently less satisfac-
tory than those in Washington. The division line between each day's work was
evident, and the entire surface was rather rough and uneven. Bridge-floor
surfaces were also constructed of these materials at Ridgewood, N. J., and
when last inspected were found to be in good condition. The estimated cost
was 46.08 cts. per sq. yd. using fluid residual petroleum, and 41.47 cts. using
cut-back petroleum residue.

Brief supplementary notes are given on the condition of roads constructed
in previous years at Youngstown, Ohio, Ithaca, N. Y., Newton, Mass., Independ-
ence, Garden City, Dodge City, Bucklin, and Ford, Kans., and at Bowling
Green, Ky.

Bituminous dust preventives and road binders, P. Hubbard (U. S. Dept.
Agr. Yearbook 1910, pp. 297-306).—The use of bitumens as dust preventives
and road binders is discussed, and the preparation, classification, selection, and
application of such materials are described. The following conclusions are
drawn:

"Bituminous road binders may be employed in the construction of earth and
gravel roads as well as macadam roads, but it is the latter type which, at the
present time, gives promise of the most satisfactory results. The bituminous
macadam, if properly constructed, seems well adapted to withstand the com-
bined action of automobile and horse-drawn traffic. It is firm, resilient, and
water-proof, and is dustless in the same sense that an ordinary asphalt pave-
ment is dustless. Much depends upon the character of the bituminous binder
used, and it is most necessary that this binder be subject to examination and
certain specific tests, as in the case of cement, iron, steel, and other structural
material."

Expt. Farm, 36 (1910), pp. 54-73, figs. 13).—The progress of the drainage cam-
paign in Ontario is discussed and a report given of the cement tile experiments
under way at the college.

The view that underdrainage increases floods is considered unwarranted, and
instances are cited wherein tile drainage has materially lessened spring freshets
and soil erosion.

In tests of making drainage tile by hand in 1909, the total cost, including
labor, of 1,000 hexagonal two-piece concrete 3-in. tile was found to be $10.64.
Trials in 1910 with another machine showed a cost for the sand and cement for
1,000 tile ranging from $3.35 for a 7:1 mixture and 3-in. tile to $11.29 for a 4:1
mixture and 6-in. tile.

In 6 experiments to test the solubility of concrete tile, small samples were
submerged in distilled water and in well water for considerable periods. No
definite rate of solution could be established, but in all samples the rate ap-
peared to fall off in distilled water, slowly in most cases, but very rapidly in a
few, especially with clay tile. In well water the samples all behaved irregular-
ly at first, giving either large losses or large gains, and these losses or gains
subsequently fell off rapidly.

Experiments with larger pieces kept in running water for 10½ months showed
a much lower rate of solution, and, on the basis of the work, it is believed there
is no danger of concrete tile crumbling under ordinary conditions. The studies
are to be continued.
Porosity was found to be increased with larger proportions of sand. "Because porosity is not essential, because it tends to increase the solubility, and because strength is a very desirable quality, we believe cement tile should be made in the proportion of 4:1 or stronger."

The danger of inexperienced men making tile of inferior quality is pointed out, and the necessity of discarding all such tile is emphasized.

Adobe as a building material for the plains, J. W. Adams (Colorado Sta. Bul. 174, pp. 8, figs. 5).—The advantages of adobe construction are discussed, directions given for the preparation and use of adobe as a building material, and descriptions presented of a cow barn, a henhouse, and a smokehouse or storeroom recently built with it at the Cheyenne Wells substation.

"An adobe house, properly built, will cost no more than a sod house and yet be as permanent, attractive, and comfortable as it is possible to build a house. They do not settle after they are dry. Mice do not work in them if they are protected at the foundation. They are superior to concrete or cement block houses in that they are nonconductors of heat and cold. They never sweat or become frosty on the inside, and rain does not wet the walls through as it does in many concrete houses. The labor required to build an adobe house is no more than that required to build a similar house of sod or concrete."

A homemade refrigerator (Survey, 26 (1911), No. 12, p. 33).—In an article quoted from the Fresh Air Magazine directions are given for a homemade device in which a bottle of milk may be kept cool by packing it in sawdust and for a similar device which requires only a small quantity of ice.

RURAL ECONOMICS.

An agricultural survey: Townships of Ithaca, Dryden, Danby, and Lansing, Tompkins County, New York, G. F. Warren, K. C. Livermore et al. (New York Cornell Sta. Bul. 295, pp. 385-569, table 4, figs. 55).—This bulletin is a summary of an exhaustive survey of the conditions that surround the business of farming and the people on farms in 4 townships of Tompkins County, N. Y., giving detailed statistics and pointing out the merits and defects of the various systems of the distribution of profits, capital, and expenses on the farm, the economic significance of the size of farms, distance from market, value per acre, labor, forms of tenure and their relation to crops grown and crops sold, soil, livestock, cattle and cattle products, systems of farming, age, and the increased earning capacity of educated farmers, together with suggestions for meeting some of the most important needs.

The relation of the size of farms to profits, receipts, expenses, and labor is illustrated by the following table:

Relation of the size of the farm to receipts, expenses, and labor—Farms operated by owners.

\[ a \text{Total amount paid for labor, value of board of laborers, value of unpaid labor by members of the family, and the farmer's labor estimated at $250 for the year.} \]

\[ b \text{Profit after deducting expenses, interest on capital at 5 per cent, and all labor as defined above.} \]
The decreased cost of labor per acre on the large farm is attributed to the increased use of farm machinery, the value of which increases rapidly with the size of the farm, it being held that farm machinery on small farms costs nearly twice as much per acre as that on the larger farms that have nearly 3 times as much machinery. The most profitable general farms in the county contain from 200 to 300 acres of tillable land.

The question as to whether a farmer should rent or own land when he has only a limited amount of capital is discussed, and illustrated as follows:

Relative opportunities for men with small capital as tenants and as owners.

On a comparison of the 3 forms of tenure, cash rent, share of crops, and share of receipts, the tenant who paid cash rent made an average labor income of $604 and those who gave one-half of the receipts $342. The landlords who rented for cash made 5.2 per cent interest, while those who rented for one-half the receipts made 9 per cent. The farmers who operated their own farms made an average labor income of $423, as compared with $379 for the tenant farmers.

It is suggested that the 3 most important points for the improvement of agriculture in Tompkins County are larger farms, better cows, and a system of farming that combines stock with cash crops.

Rural economy in the Bombay Deccan, G. F. Keatinge (Agr. Jour. India, 5 (1910), No. 4, pp. 392–318; 6 (1911), No. 2, pp. 115–131).—The author discusses and illustrates the several systems of land tenure, the economic advantages of small holdings and irrigation wells, the disadvantages of the custom of tenants to live in villages, the serious drawbacks to the efficiency of labor, and the apparent high rate of interest, which ranges from 4 to 24 per cent for loans with land as security, and as much as 100 per cent for loans on personal security, this being attributed to the scarcity of capital, lack of organization, possibility of loss, trouble involved in collecting the interest, and the personal enmity which the village money lender often incurs.

First prize five-acre farm plan, A. Oppermann (Missouri Bd. Agr. Mo. Bul., 8 (1910), No. 10, pp. 5–11, pl. 1).—This bulletin contains the plan for buildings and grounds for the 5-acre farm awarded the first premium in what is known as the 5-acre farm contest conducted by the Missouri State Board of Immigration in June, 1910. A discussion shows in a plain and practical way how a man of limited capital may concentrate his energies on a small tract of land and make a reasonable good living for himself and family.

[Some farm problems], H. Wallace (Ann. Rpt. Nebr. Bd. Agr., 1910, pp. 124–133).—In this address before the Nebraska State Board of Agriculture the speaker discusses the following rural problems: Maintenance of soil fertility, farm labor, agricultural education, and a social organization of farm life.
The farmer and the consumer.—Can they be brought together? (Country Gent., 76 (1911), No. 30/4, p. 521).—This article discusses and illustrates the relations between the laws of production and consumption, pointing out that production from the soil has never kept pace through a series of years with consumption, and showing that the low prices received by the farmer for his produce are not caused by overproduction but by underconsumption, due to the methods or system of present-day marketing. It is suggested that the producer and ultimate consumer could simplify the perplexities of marketing and lighten the burdens of each by simple and direct cooperation.

Credit cooperative societies in Russia and their intermediacy in joint purchases and sales, S. V. Borodaevski (Ezh. Depl. Zeml. [Russia], 29 (1908), pp. 289-300, pl. 1).—In 1895 the Russian government established for the first time credit cooperative societies in which the members must be stockholders, but the financial operations of which are conducted with capital obtained from the Russian treasury, from private deposits, and from loans. By the law of 1904, the so-called loan and savings societies, private institutions which had been existing in Russia for several decades, were caused by the government to closely conform to the credit cooperative societies.

In 1909 there were in Russia 1,644 loan and savings societies and 3,133 credit cooperative societies, with about 2,000,000 members. Peasants form the majority of the membership. The financial statements of 902 loan and savings societies on January 1, 1907, and of 2,635 credit cooperative societies on January 1, 1909, show total resources amounting to 100,000,000 rubles ($35,000,000), and a total of loans advanced amounting to $4,000,000 rubles. These societies, in addition to advancing loans, gradually extend their operations in joint purchases of materials required by the members and in selling the articles produced by them.

Ameliorative credit in Russia, S. I. Slastnykov (Ezh. Depl. Zeml. [Russia], 30 (1909), pp. 668-703).—Credit organization by the Russian government for agricultural improvements had its beginning in 1890, but little progress was made until 1900, when new regulations were introduced which greatly stimulated the applications and granting of loans for various improvements. From 1901 to 1904, the allowing of credit gradually increased, but with the beginning of the Japanese War the appropriations for ameliorative credit were suspended until 1908, when the government again began to make appropriations for granting loans to peasants and farmers.

The loans allowed in 1908 and 1909 amounted to 1,915,461 rubles ($976,886.64). The interest charged is 3 per cent, except on loans for strengthening the shores of rivers, ravines, and quicksand when it is only 2 per cent. The kind of improvements and number of loans with amounts of capital allowed in 1909 were as follows: Drainage, 92 loans, 454,378.75 rubles; irrigation, 113 loans, 229,594 rubles; strengthening of soils, 11 loans, 10,962 rubles; forest planting, 2 loans, 3,056 rubles; orchards, 31 loans, 27,782 rubles; vineyards, 5 loans, 10,600 rubles; wine making, 1 loan, 3,500 rubles; grass sowing, 5 loans, 41,020 rubles; clearing of lands, 4 loans, 3,312 rubles; agricultural buildings, 20 loans, 55,554 rubles; agricultural establishments, 10 loans, 19,525 rubles; farming, 1 loan, 1,610 rubles; breeding cattle, 16 loans, 21,230.5 rubles; sundry improvements, 11 loans, 20,500 rubles; and butter-making cooperative societies, 96 loans, 117,875 rubles.

Supply and wages of farm labor, G. K. Holmes (U. S. Dept. Agr. Yearbook 1910, pp. 158-200).—The author points out that the attractions of the city and the city's illusions of higher wages are robbing the farm of its laborers, showing that 3.1 per cent of the number of persons having gainful occupations in the United States in 1820 were engaged in agriculture, 44.1 per cent in 1850, and 35.3 per cent in 1900. It is shown that the introduction of farm machinery has
increased the productiveness of labor and decreased the proportionate number of agricultural laborers. Especially is this true of the female element of agricultural labor for hire generally and negro labor in the South, it being held that more than one-half of the cotton is now raised by white labor. From 1855 to 1894 the time of human labor required to produce 1 bu. of corn on an average declined from 4 hours and 34 minutes to 41 minutes, and that of 1 bu. of wheat from 3 hours and 3 minutes in 1830 to 10 minutes in 1894.

The idea that agricultural labor is not paid as much in proportion to other labor seems to be controverted by the author, who points out that the money wages, together with the supplementary allowances and the lower cost of living of the farm laborer, in the end amount to more than he can earn in any occupation open to him in the city.

Farm labor from the city. H. H. Lyon (Country Gent., 75 (1910), No. 3022, p. 1217).—The author in discussing the possibility and advisability of getting farm labor from the city is doubtful whether such labor would be very satisfactory to the farmer should he get it, and whether it would remain long. He thinks it economically safer and possibly more profitable if the farmer would "cut down a little the amount of business he does," and depend largely upon himself and upon his country conditions to handle it.

Requirements and cost of animal power and motor power in agriculture, Strebel (Fühling's Landw. Ztg., 60 (1911), No. 11, pp. 361-377, fig. 1).—This is a comprehensive discussion of the requirements and cost of animal power in agriculture and of the possibilities of substituting motor power instead.

The history of the agricultural tariff. H. Hertel (Tidsskr. Landökonomi, 1911, Nos. 3, pp. 133-174; 4, pp. 255-270).—This is a historical sketch of tariff legislation pertaining to agricultural production in European countries.

[Agricultural production in Spain from 1890 to 1910]. D. E. de la Sotilla (Bol. Agr. Tec. y Econ., 3 (1911), No. 27, pp. 264-275).—Statistical tables are given, showing the acreage and average production and the total value of the principal agricultural products on dry and irrigated lands in Spain in the last decade of the nineteenth century and the first decade of the twentieth.

Foreign crops, June, 1911, C. M. Daugherty (U. S. Dept. Agr., Bur. Statis., Circ. 20, pp. 13).—This circular presents data as to the acreage, yield, imports, and exports of some of the principal agricultural products and the condition of growing crops in foreign countries in June, 1911.

AGRICULTURAL EDUCATION.

The origin of the Land-Grant Act of 1862 (the so-called Morrill Act) and some account of its author, Jonathan B. Turner, E. J. James (Univ. Ill., Univ. Studies, 4 (1910), No. 1, pp. 139).—In his main argument the author seeks to prove that Jonathan B. Turner, at one time professor in Illinois College at Jacksonville, Ill., was the real father of the so-called Morrill Act of July 2, 1862, and that he deserves the credit of having been the first to formulate clearly and definitely the plan of a national grant of land to each State in the Union for the promotion of education in agriculture and the mechanic arts, and of having inaugurated and continued to a successful issue the agitation that made possible the passage of the bill.

An appendix contains reprints of several documents considered in the case including a letter from Senator Morrill to Professor Turner, and a pamphlet on Industrial Universities for the People, published by Professor Turner. This pamphlet, published in 1853, outlines work for the proposed system of industrial universities along lines closely approaching the actual development in the land-grant institutions.
Agricultural experimentation and instruction in North America and Germany, K. von Rümker (Ztschr. Landw. Kammer Schlesien, 15 (1911), No. 20, pp. 618-627).—In a comparison of agricultural experimentation and instruction in North America and Germany, the author reaches the following conclusions for Germany: (1) That the apportionment of higher educational institutions to two different authorities is not advantageous, (2) that a further clearer specification in experimentation and instruction is necessary, (3) that the existing grading in agricultural instruction no longer fully meets the present needs of the agricultural youth, and above all that the special or technical training of the small farmer is insufficient, and (4) that the agricultural publication service is inadequate and gives too little consideration to small farming.

Agricultural schools, D. J. Crosby (Ann. Rpt. Comr. Agr. Vt., 2 (1910), pp. 165-173).—This address includes a discussion of the present status of secondary instruction in agriculture in the United States, including types of schools teaching secondary agriculture, the function of agriculture in public high schools, and the functions of the special agricultural school. It is concluded that the influence of agricultural high schools is to stimulate rather than to retard the introduction of agriculture into public high school courses, and that they do not reduce the attendance at the colleges of agriculture.

Agricultural education in the common schools, E. Hyatt (Rpt. Col. State Agr. Soc., 1910, pp. 41-43).—The object of this paper is to call attention to and emphasize the fact that we must find something different from the traditional text-book method of approach if we would really get the genius of agriculture into the public schools. Two or three other methods of approach are mentioned. It is suggested that the best plan for a school to undertake agriculture is by finding ways to cooperate personally with the nearest agricultural industry, by actually entering into its spirit and its labors.

Transforming a country school, Mabel Carney (Farmers Voice, 49 (1911), No. 121, pp. 10, 11, 19).—This article describes how a teacher in a one-room country school in Illinois changed the physical surroundings of the school building, remodeled the course of study, and made the school a social center for the people of the community.

Community work in the rural high school, D. J. Crosby and R. H. Crockett (U. S. Dept. Agr. Yearbook 1910, pp. 177-188, pls. 4).—Some influences that have a bearing upon the evolution of the rural high school are discussed, a general account of community work in such schools is given, the different forms of community work are outlined, and the details of such work as carried on in the Agricultural High School of Baltimore County, Md., are given. These have included meetings and courses of instruction for rural school teachers, adult farmers, and farmers' wives, and literary meetings, field days, and other exercises for children.

Cotton growing for rural schools, G. W. Carver (Alabama Tuskegee Sta. Bul. 20, pp. 5-29, figs. 8).—Considerable information is here given relative to the preparation of the seed bed, fertilization, planting distance, and thinning, cultivation, grading and marketing, the American classification, diseases and insect enemies, products from a ton of cottonseed, how to collect an exhibit, and the various methods of cotton improvement.

Illustrated corn booklet, O. H. Benson (Jour. Ed. [Boston], 73 (1911), No. 20, pp. 543, 544).—This article consists of suggestions and directions on the arrangement of a notebook on corn, as well as of the specific material that may be placed on each page. It is suggested at the close that in a general way this corn booklet plan may be used in developing the work in many farm and
home subjects such as potatoes, poultry, bread making, home decorations, balanced rations, the model kitchen, crop rotation, etc.

The school garden, LANDMANN (Gartenwelt, 15 (1911), No. 21, pp. 281–286, dgm. 1).—The author gives suggestions for an ideal school garden, including a plan and description of a school garden adopted by the Realgymnasium at Biebrich on the Rhine.

Home vegetable gardening, C. S. Heller (Facts for Farmers [Mass. Agr. Col.], 1 (1911), No. 11, pp. 4.)—The facts here brought out have to do with the location of the home vegetable garden, its plan and arrangement, the location of crops, fertilizers, varieties of vegetables that have proved satisfactory under average home garden conditions, and a vegetable planting table adapted to northern conditions.

Farm demonstration work in North Carolina, C. R. Hudson (Prog. Farmer, 26 (1911), No. 26, pp. 589, 581).—This article enumerates the purposes of the farm demonstration work in North Carolina and shows in detail what it has accomplished and what are the prospects for the future.

MISCELLANEOUS.

Yearbook of the Department of Agriculture, 1910 (U. S. Dept. Agr. Yearbook 1910, pp. 711, pls. 49, figs. 31).—This contains the report of the Secretary on the work of the Department during the year; 28 special articles abstracted elsewhere in this issue; and an appendix containing an article on the Publications of the U. S. Department of Agriculture and How They are Distributed, by J. A. Arnold; Review of Weather Conditions of the Year 1910, by P. C. Day; Seed Time and Harvest—Average Dates of Planting and Harvesting in the United States, by J. R. Covert; a directory of the Department, the agricultural colleges, the experiment stations, and State officials in charge of agriculture; and agricultural statistics in which the domestic production, prices, and commercial movement of the principal crops and farm animals have been presented with even greater fullness than heretofore.

Twenty-third Annual Report of Georgia Station, 1910 (Georgia Sta. Rpt. 1910, pp. 167–175).—This contains the organization list, reports by the president of the board of directors and by the director of the station on its work during the year, and a financial statement for the fiscal year ended June 30, 1910.

Annual report of the director for the fiscal year ending June 30, 1910 (Delaware Sta. Bul. 92, pp. 8).—This contains the organization list and the report of the director on the work of the station. It includes a financial statement for the fiscal year ended June 30, 1910.

Monthly Bulletin of the Department Library, April, May, and June, 1911 (U. S. Dept. Agr., Library Mo. Bul., 2 (1911), Nos. 4, pp. 91–126; 5, pp. 121–158; 6, pp. 159–184).—These numbers contain data for April, May, and June, 1911, respectively, as to the accessions to the Library of this Department and the additions to the list of periodicals currently received.

NOTES.

Delaware College and Station.—W. C. Pelton has been appointed assistant horticulturist and M. O. Pence assistant agronomist, their work to be largely in connection with the extension division. Dr. C. F. Dawson, for several years professor of veterinary science and bacteriology in the college and veterinarian in the station, has resigned, this taking effect October 1.

At a Farmers' Day recently held at the college farm it was estimated that between 2,500 and 3,000 farmers were in attendance.

Massachusetts College and Station.—Plans have been completed for the new dairy building, for which an appropriation of $75,000 was made by the last legislature. This is to be a three-story fireproof structure, of dark red brick with granite foundations, with 60 feet frontage and 120 feet in depth.

The main floor will contain milk receiving rooms, washing and sterilizing apparatus, bottling and shipping rooms, refrigerators, an ice cream plant, and the separator, cream ripening, and churning rooms. On the second floor will be a dairy bacteriological laboratory, a milk testing laboratory, a laboratory for advanced students, and a dairy museum. A cheese room and a cheese ripening room, a laundry, an ice making plant, and a dairy machinery laboratory will be located in the basement. A unique feature of the building will be the observation corridors on each floor, by means of which visitors may watch operations going on in the different rooms without actually entering them.

Sumner C. Brooks, assistant in botany and vegetable pathology, has resigned, this taking effect September 15, and is succeeded by Edward A. Larrabee.

Ohio State University.—The students who took the course in agricultural education at the summer session have formed an association, known as the Ohio Association for the Advancement of Agricultural Education, which now has members in nearly every county in the State. One feature of the organization is a bureau of information, of which Prof. G. A. Bricker of the College of Agriculture is director, and the professors in charge of agricultural education in the other state institutions are members. The function of this bureau is to collect and publish information of value to members of the association.

Clemson College.—The Farmers' Union Sun for August 11 states that the trustees have authorized the organization of a work-boy course in agriculture. Into this class 20 students will be received at the opening of the coming session. They will be divided into two squads of 10 men each. One squad will work as laborers on the farm for a week, while the other squad will attend classes. At the end of each week, the squads will interchange and in that way alternate weeks will be devoted to farm work and to study. The course will be completed in two sessions. These boys will receive from 75 cents to $1 per day. A knowledge of reading, writing, and arithmetic is the only scholastic requirement for admission.

**Note.**—The price of *Experiment Station Record* is $1 per volume, and two volumes are issued annually. It may be purchased from the Superintendent of Documents, Washington, D. C., to whom all remittances should be made. The publications of the State experiment stations are distributed from the stations and not from the Department.
Two men have recently passed from the stage of action in Europe whose names are linked with the progress of agricultural experimentation—one an organizer and administrator, as well as a teacher, experimenter and writer; the other perhaps the foremost investigator in animal nutrition of his time, and likewise a teacher and writer of wide influence.

These men, Louis Grandeau, of France, and Oskar Kellner, of Germany, are known wherever the history and the results of agricultural investigation are known. Appreciated and honored at home by the State and by their colleagues, as also by the practical farmers, the influence of their work and their writings has extended far beyond the boundaries of their own countries. Both were directors of the first experiment stations established in their respective countries, Grandeau of the Experiment Station of the East, which was founded at his instigation at Nancy in 1868 as the first station in France, and Kellner, for the past eighteen years director of the famous Möckern Station, the forerunner of all the institutions of this class. Both men were likewise active in the editorial field, being the editors of the organs of the French and German experiment stations, respectively, and of popular journals relating to their work. And by a singular coincidence they died on the same day—September 22, 1911—Grandeau in Interlaken, where he was sojourning in the effort to recover his health, and Kellner at Karlsruhe, whence he had gone to preside at the annual meeting of the Association of German Experiment Stations.

The agricultural press of both countries have vied with one another in honoring the memory of these men, and in setting forth the exceptional and lasting character of their services; and for us in America, where their works were so widely known to readers of science, a brief review of their lives will serve to refresh the memory of their services and to record the appreciation in which they were held.

Louis Grandeau, professor of agriculture in the School of Arts and Trades in Paris, inspector general of experiment stations, and director of the Agricultural Station of the East, and sometimes referred to as the "grand old man of agricultural science in France,"
was born May 21, 1834, at Pont-à-Mousson, in the Department of Meurthe-et-Moselle, Lorraine. He was, therefore, in his seventy-eighth year at the time of his death.

After graduating from college he pursued graduate work for the doctorates in science and medicine and for the diploma of pharmacy. For ten years he worked under the direction of Sainte-Claire-Deville at the École normale supérieure, and under Claude Bernard at the College of France, where he did original research work on the presence of cesium and rubidium in alkaline waters. He further gave attention to the alkaloids, methods of water analysis, and other lines of chemical study. At this period he became especially interested in organic chemistry and physiological studies, out of which grew his attention to the application of these branches in agriculture, and which furnished the basis and motive of his life work.

In 1867 he was sent to Germany by the French Ministry of Agriculture to study the experiment station system of that country. He was much impressed with the importance of the agricultural laboratories and experiment stations which had been established and with their practical value to agriculture, and he undertook the work of establishing such institutions throughout France.

On his return he laid his plans for the founding of a station before the Ministry of Agriculture, and received a grant which enabled him to open, in 1868, the Experiment Station of the East on his own estate, located near Nancy, as the first French station. In the same year he was appointed to the new chair of chemistry and physiology, as applied to agriculture, in the University of Nancy, and was invited to give a course of lectures on agricultural chemistry, an opportunity which, as he says, he accepted with enthusiasm in the hope that he might stimulate the improvement of agriculture in his native State.

During the first years of his work at Nancy he gave special attention to the physiology of plants and conducted special researches on the function of the organic matter of the soil in plant nutrition. In connection with these studies on soil humus, or matière noire, as he termed it, he devised a method for its determination which has remained in quite general use to the present time. With Fliche he investigated extensively the lack of tolerance of certain plants for lime, controverting the then widely accepted view of Thurman which attributed the distribution of the native floras to physical conditions of the soil. He also at this time began his observations on the influence of atmospheric electricity upon plant growth.

His studies of methods of analysis resulted in the publication of a volume on agricultural analysis (Traité d'analyse des matières agricoles) in 1877, which has passed through three editions, the last of which, a two-volume work, was published in 1897. This treatise was translated into German and Italian.
Grandeau had realized from the first that an experiment station needed not only a laboratory, but also experimental fields. His field work was conducted at the outset in part upon his own estate, and when the Mathieu de Dombasle School of Agriculture was established at Tomblaine near Nancy, he saw to it that such fields were provided. Here he carried on his cultural and fertilizer experiments for years, and when the station was transferred to the vicinity of Paris in 1890, he secured land for his field work at the Parc des Princes, in the immediate vicinity of the city.

Grandeau conducted an active campaign for the establishment of similar stations in various parts of the Republic, and was a large factor in this movement. In 1881 he was appointed inspector general of the stations, a position he held until the close of his life, which gave him a wider opportunity for the exercise of his influence. He established the *Annales de la Science Agronomique*, which was published under the auspices of the Ministry of Agriculture, as an organ of the agricultural stations and laboratories of France, for the dissemination of their detailed work, and for bringing to their notice the work of stations in other countries. He remained in active editorial management of this journal nearly to the close of his career.

Grandeau was an earnest advocate of the demonstration fields, which early became a feature of the campaign for the improvement of agriculture, and urged their establishment and extension throughout the Republic. These fields, of which there are more than three thousand, were designed to bring the results and applications of the teachings of the stations to the attention of farmers by ocular demonstrations on small areas. On one occasion he said in advocating them: "If every town of France could have a demonstration field, the agricultural aspect of the country would be changed in a few years and the primary benefit to the peasant would redound to the benefit of the country as a whole." These fields are ranked among the most powerful agencies for increasing and improving agricultural production in that country.

In 1872 one of the omnibus companies of Paris decided to establish a laboratory for the purpose of carrying on experimental work with reference to the rational feeding of horses, and Grandeau was intrusted with the task of organizing this laboratory and directing its work. His activities in that direction continued through many years, and led to a wider interest in both human and animal nutrition, to which subjects he gave much attention during the last years of his life. In 1905 he summarized the results of twenty years' investigation with work horses, giving practical deductions as well as theoretical conclusions.

As a teacher Grandeau's influence was exerted both in the classroom and through the press. At the age of twenty-five he was pro-
fessor of chemistry for the Philotechnic Association, which gave free instruction to the workmen of Paris. For twenty years he was professor on the faculty of sciences at the University of Nancy, which conferred upon him the office of dean. During this period he was also professor of agriculture at the National School of Forestry. When he left Nancy to locate in Paris he was called to the chair of agriculture in the National School of Arts and Trades, retaining this position until a year ago.

As a writer he was unusually prolific, having a very long list of reports and articles to his credit. No author's name has appeared so frequently as his in this journal. His articles were in part reports of his studies and in part popular accounts of the work of others and their applications in practice. He covered a wide range both in his studies and in his writings—fertilizers, soils, climatic influences, the manuring and culture of crops, the physiological functions of plants and animals, the feeding of live stock, methods of analysis and of investigation, statistics, and the nutrition of man were all within the purview of his wide activity. In 1879 he published a book on the nutrition of plants, in 1893 one on animal nutrition, and in the same year a popular work on the use of fertilizers and manures.

Few men have been more active or successful in the popularization of agricultural science and in bringing its teachings into practice. As far back as 1861 when the *Temps* was founded, he became its agricultural editor and served in that capacity for a long series of years. In 1867 he began contributing to the *Journal d'Agriculture Pratique*, and in 1893 he was made its editor in chief. Under his direction this journal became known throughout the world as an accurate and reliable source of information.

Grandeau was a natural leader in agricultural affairs, who was turned to in connection with large public enterprises. He arranged for and directed the International Congress of Experiment Stations in 1881 and 1882, and prepared a report on the latter gathering. In addition to the proceedings, this report contained a large amount of statistical information regarding the history, organization, work, and publications of the experiment stations throughout the world, together with articles on special subjects in agricultural science. He was reporter for the international jury on agronomy and agricultural statistics at the Paris Exposition of 1889, and likewise for the international jury on agriculture and horticulture at the exposition of 1900, publishing voluminous and valuable reports on each occasion.

To him was also assigned the task of preparing the general report on agriculture at the Paris Exposition of 1900. This he made a comprehensive review of the agriculture and the agricultural institutions of the world at the close of the nineteenth century, a work of four large volumes. This was the last great accomplishment of his life.
and was a work in which he took great pride. It will remain as a monument to his industry and his broad grasp of the subject.

Public recognition of the services and the place occupied by Grérandeau are evidenced by the honors and offices conferred upon him. In addition to the positions already mentioned, he was a member of the Superior Council of Agriculture, of the National Society of Agriculture, and vice president of the Society for the Encouragement of Agriculture in his own country, and was also elected to membership in the Royal Society of England, the Imperial Agricultural Society of Moscow, the Royal Agricultural Academies of Turin and of Sweden, and many others. In 1900 the French Government conferred upon him the order of Commander of the Legion of Honor, and in 1908 the National Society of Agriculture awarded him a gold medal in consideration of the services rendered by him for more than 50 years, an honor which the history of his active life highly merited.

Oskar Kellner, director of the agricultural experiment station at Mönchern, Germany, was born May 13, 1851, at Tillowitz, near Falkenberg, in the Prussian Province of Silesia. Following the Franco-Prussian War, in which he took part, he studied chemistry and the natural sciences at the universities of Breslau and Leipsic, taking special work at the latter institution under Knop and Sachsse, and made his doctorate at Leipsic in 1874. For two years following he was assistant in the experiment station for animal physiology at Breslau, under Hugo Weiske. This position gave him opportunity to enter upon the field of investigation in which he was later to make such notable contributions.

In 1876 he went to the experiment station at Hohenheim, where under Emil von Wolff, one of the founders of the modern theories of animal nutrition, he continued investigations in this line, one of his notable studies on the effect of muscular activity on the metabolism of the horse being a product of that period. It is an interesting and significant fact that at this early date, four years before the publication of Rubner's epoch-making paper on the replacement values of the principal organic nutrients and nine years before Lehmann, Zuntz, and Hagemann's first respiration experiments on the horse appeared, we find Kellner investigating the utilization of the potential energy of carbohydrates and of fats in work production, and devising a general experimental method for this purpose, substantially according to which the subsequent experiments at Hohenheim were made.

From 1881 to 1893 Kellner was professor of agricultural chemistry in the University of Tokio, being likewise technical adviser in the ministry of agriculture and commerce. Here he continued his researches, publishing a long series of papers in collaboration with his
students. The establishment of experiment stations throughout Japan and the introduction of commercial fertilizers in that country are attributed largely to his efforts.

Following his twelve years in Japan, in 1893 he was appointed director of the Möckern Experiment Station to succeed Gustav Kühn, who had died the previous year. The eighteen years which followed was the period in his life which made him famous as a leader in the advanced theories of animal nutrition. He brought to his work a thorough preparation, a keen perception, and an energy and perseverance which were the foundations of his success.

His first undertaking was to compile and publish the work left by his predecessor, covering a period of nearly twenty years and representing a large part of the life work of this eminent investigator. This summary was issued in 1894, occupying an entire volume of Die landwirtschaftlichen Versuchs-Stationen, nearly six hundred pages.

Kühn had followed in the lines of Henneberg and Stohmann in employing the respiration apparatus to study the utilization of feeding stuffs under different conditions. Kellner supplemented the respiration experiments with calorimetric determinations of the energy value of the feeds employed and of the animal excreta, in accordance with the teachings of Rubner, and by this means established nutritive values for many feeding stuffs and their individual constituents. As subjects he employed full-grown steers and oxen, and later milch cows, while Zuntz studied in a similar way the nutrition of the horse.

This new point of view, which involved the study of the metabolism of both matter and energy under different conditions of feeding, resulted in marked advance in the theory of nutrition. It showed that like amounts of digestible nutrients in different feeds have different values and that the energy required for digestion and losses due to decomposition, etc., must be taken account of in arriving at the net or available values. This conception of the gross energy as having a varying net value furnished the basis for a new means of estimating net values of feeding stuffs, and upon this basis Kellner worked out his system of “starch values” as a means of comparing feeds and calculating rations.

Kellner’s investigations on the metabolism of matter and energy in cattle covered seventeen years of work and included both maintenance and fattening conditions. He also studied the energy and nutrient requirements as a basis for the refinement of the feeding standards, and determined the digestibility of numerous materials and the action of the individual nutrients. A long list of new feeds was studied, including the molasses preparations; and his experiments were extended to milch cows to determine the action in milk production of various classes of feeds.
Kellner’s work illustrates the skill and the industry of the man and his mastery of this intricate subject. Its brilliant and advanced character ranked him with the foremost leaders in the world, and made him a worthy successor to such men as Wolff, Henneberg, and Kühn.

The theories and reforms worked out by Kellner were embodied in his well-known book on the nutrition of farm animals (Die Ernährung der landwirtschaftlichen Nutztiere), an important product of his life work, published in 1905, which rapidly passed through five editions. This was followed by a smaller manual on the principles of feeding (Gundzüge der Futterrungslehre), three editions of which have appeared, and which has been translated into several languages.

Since 1905 Doctor Kellner had edited Die landwirtschaftlichen Versuchs-Stationen, the organ of the German experiment stations and one of the foremost periodicals of its kind in the world; and since 1902 he had been in editorial management of the Zentralblatt für Agrikulturchemie, a standard abstract journal of wide scope. He was also a frequent contributor to the leading agricultural press of Germany, and since 1907 had furnished the data and discussion on feeding for the Landwirtschaftlicher Kalender, in which his starch values were employed. In recent years he had published several summaries of cooperative feeding trials on horses, cattle, and swine.

So far as his time permitted he entered energetically into the activities of various agricultural bodies and of the German Agricultural Society. He had been a member of the executive committee of the latter society since 1904, and had frequently taken part in its meetings and delivered many addresses before its sections. A few weeks before his death he had accepted election to the special committee on feeding and was to have entered at once upon its work. Kellner’s experience also made him a leading force in the German Agricultural Council, a national organization composed of representatives from various parts of the Empire; and he was a member of the Agricultural Council of Saxony, and on the advisory council of the Imperial Biological Institute for Agriculture and Forestry.

Since 1903 Kellner had been president of the Association of German Experiment Stations, and was an active worker in it for many years. He felt the responsibility of the control work with which his station was charged, and gave his personal attention to trade relations and questions involved in this control. He had the courage of his convictions when once his mind was made up, and stood uncompromisingly for what he considered to be the right. He did not fail the association in offensive or defensive steps to maintain its position or enforce its obligations.
Many honors had come to Doctor Kellner in recognition of his services. The Order of the Red Eagle, third class, was conferred upon him by the Government, and he was named *Geheimer Hofrat*. The Swedish Academy of Agriculture made him a member, and on the occasion of the jubilee celebrating the one hundredth anniversary of the University of Breslau last year the medical faculty conferred upon him the highest academic recognition—its honorary degree of doctor of medicine, an honor of which he was justly proud.

Doctor Kellner had attended the International Dairy Congress at Stockholm the past summer and returned in full health and vigor. He went to Karlsruhe to preside at the convention of the Association of German Stations and was stricken with apoplexy on the eve of its meeting. His death, at the premature age of sixty years, came, therefore, as a great shock to his friends. He was to have retired from the office of president this year, and the decision had been reached to confer on him the title of honorary president in recognition of his prolonged service.

In announcing Doctor Kellner’s death to the association, Professor Fresenius said of him: “As a conspicuous man of science he was an ornament to the association. He was one of the best among us—a noble man from head to foot. His memory, the grateful recollection of his service, will long remain with us.”
RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Handbook of biochemistry, edited by C. Oppenheimer (Handbuch der Bio-
593-736+96, fig. 1).—These parts of this handbook contain the following chap-
ters: Chemistry of the lungs and chemistry of new formations, excretory
glands and excretions, including the chemistry of normal and pathological
urine, urinary sediments and concrements, and the physical chemistry of the
urine, amniotic fluid, energy exchange, and interchange of material between
mother and fetus.

The nature of enzym action, W. M. Bayliss (London, New York, and Cal-
cutta, 1911, 2. cd., pp. XI+137, figs. 7).—This is the second edition of this
book, and deals with catalysis in general, enzymes as catalysts, physical and
chemical properties of enzymes, general methods of preparation and of investi-
gation, reversibility of enzym action, the velocity of reaction and the various
conditions affecting it, the nature of the combination between enzyme and sub-
strate, coenzymes and antienzyms, zymogens, and oxidation processes and cer-
tain complex systems. A list of literature and some supplementary notes are
appendend.

Catalase, F. Battelli and L. Stern (Ergeb. Physiol., 10 (1910), pp. 531-
597; abs. in Chem. Abs., 4 (1910), No. 22, p. 308).—This is a general review of
the subject and deals with the isolation, properties, and mode of action of cata-
late. It gives comparisons in regard to the action of different metals on
hydrogen peroxid and the effect of different agents, such as light and electricity,
on the activity of the reaction and the nature of the mechanism of the reaction.
The relation of catalase to reductase, oxidase, peroxidase, and the distribution of
catalase in animal and plant tissues are discussed. Anticatalase, phlocata-
lase, and some hypotheses are also described. (See also a previous note, E. S. R.,
24, p. 411.)

Preparation of the 24-hour lactic acid yeast (Pure Products, 6 (1910), No.
10, pp. 399-601, fig. 1).—A description of a quick lactic acid yeast-producing
apparatus.

Action of the Bulgarian ferment upon the proteins and amidis, J. Effront
(Compt, Rend. Acad. Sci. [Paris], 151 (1910), No. 22, pp. 1007-1009).—The
author has continued his studies on the action of the Bulgarian ferment (lacto
bacilllin) upon certain proteins and their derivatives, using barley germ deco-
tion, peptone (with and without glucose or asparagin), and milk, and in the
presence of calcium carbonate.

The results show that the acidity formation is much in excess of the sugar
decomposed, but that ammonia is simultaneously produced. In the case of
milk the acids present were found to be acetic, formic, propionic, succinic, lac-
tic, and malic. Casein and albumin were completely decomposed.

(See also a previous note, E. S. R., 21, p. 21.)

In regard to the action of the Bulgarian ferment upon protein substances,
G. Bertrand (Compt, Rend. Acad. Sci. [Paris], 151 (1910), No. 24, pp. 1161,
1162; abs. in Centbl. Bakt. [etc.], 2. Abt., 30 (1911), No. 19-20, p. 501).—The
12544°—No. 7—11—2
609
Bulgarian ferment was found to attack casein to only a very small degree. In this respect the author's findings do not agree with those of Effront noted above, and the author believes that the latter had a contamination with some foreign organism.

In regard to the Bulgarian ferment, J. Effront (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 8, pp. 363-365; abs. in Centbl. Bakt. [etc.], 2. Abt., 30 (1911), No. 19-20, pp. 501, 502).—The author has continued his work in this direction, and now reports the results with Bertrand's Bulgarian ferment and Jaourt's ferment (Lactobacilline, Maya bulgare, and Maya nutricia). All the latter preparations mentioned converted milk to a yellow fluid, while Bertrand's ferment produced a jelly-like coagulum.

The results in detail were as follows: The percentage of nitrogen in the form of amids was 16.2 for Bertrand's Bulgarian ferment and from 71 to 87 for Jaourt's artificial preparation, the total acidity expressed as tenth-normal alkali in 100 cc. solution was 250 cc. for Bertrand's ferment and from 78 to 110 for Jaourt's; and the volatile acid expressed as tenth-normal alkali per 100 cc. was 18 cc. for Bertrand’s ferment and from 55 to 88 for Jaourt's.

Contributions to the biology of colostrum, J. Bauer (Deut. Med. Wchnschr., 35 (1909), No. 38, pp. 1637-1639; abs. in Hyg. Rundschau, 20 (1910), No. 11. pp. 616, 617).—An antisera was prepared with which it was possible, with the aid of the complement binding method, to differentiate colostrum from cow's milk. The antisera deviated with the same colostrum in dilutions up to 1:100,000, but with cow's milk and bovine serum it was only specific in dilutions of 1:10,000. The colostrum of the first day evidently contains bodies which act as antigens and which are also contained in the blood serum but not in the milk of the same type of animal. First-day colostrum is also hemolytic for guinea-pig corpuscles, while milk is not.

The relation between milk, colostrum, and serum of the cow, F. Graetz (Ztschr. Immunitatsf. u. Exptl. Ther., 1. Orig., 9 (1911), No. 5. pp. 677-708; abs. in Chem. Abs., 5 (1911), No. 15, 2500).—It was determined with the precipitin, anaphylaxis, and complement-fixation tests that there is only a quantitative relation between these 3 fluids and not a qualitative one. Colostrum takes the intermediate position.

Estimating the fat in milk by the Rose-Gottlieb method, C. Huyge (Rev. Gen. Lait, 7 (1909), No. 12, pp. 265-272; abs. in Molk. Ztg. [Hildesheim], 24 (1910), No. 13, p. 218).—Tests were conducted with Rohrig's apparatus, and the results show that the upper etheral layers contain more fat than the lower ones. The author claims that better results may be obtained if the glass cock of the apparatus is placed lower down and the whole etheral layer is used for the determination. Two washings are made with ether after drawing off the fluid. (In this regard see also a previous note (E. S. R., 23, p. 217.).

A note in regard to the estimation of fat by the modified Rose-Gottlieb method, C. Huyge (Rev. Gen. Lait, 8 (1910) No. 14, pp. 326-328, fig. 1).—The author found the Eichloff and Grimmer siphon method (E. S. R., 23, p. 217) to furnish good results.

blue. It has the advantage of giving a better solution of the proteins, etc., of the milk, is easier and cleaner to handle, and the final temperature of 45° C. makes it easier to get a proper reading of the fat column.

Thirty-five samples of milk were tested, including skim, sour, and sweet whole milks, and cream, preserved with formaldehyde, potassium bichromate, and copper sulphate. When compared with other methods, such as the old acid butyrometric method and Gottlieb’s (E. S. R., p. 499), it was noted that the “neu-sal” gave the highest results. With boiled milk the reagent is not a good one.

The “neu-sal” method, W. GRIMMER (Milchw. Zentbl., 6 (1910), No. 9, pp. 409, 410).—Comparative tests were made between the “neu-sal” acid butyrometric and Rose-Gottlieb methods, which show that the “neu-sal” method has no particular advantage in regard to the technique over the acid butyrometric method. In most instances it gave lower results than the Rose-Gottlieb method.

Wendler’s “neu-sal” method for estimating fat in milk, M. SIEGFELD (Molk. Ztg. [Hildesheim], 24 (1910), No. 38, pp. 713, 714).—A comparative test between the acid butyrometric, the “neu-sal,” and Rose-Gottlieb methods is reported, in which it is shown that the “neu-sal” method yields good results and has the additional advantage of not corroding the apparatus, injuring the hands, etc.

Utilizing the “neu-sal” method for sheep and goat’s milk, C. BEGER (Milchw. Zentbl., 6 (1910), No. 9, pp. 410–412).—The author conducted tests with the acid butyrometric apparatus and the “neu-sal” reagent diluted once, and he concludes that the method furnishes a test which is free from danger in the hands of the laity. The results compare well with those obtained with the acid butyrometric method. The method can not, however, be employed where milk is preserved with large amounts of formaldehyde.

The “neu-sal” method, O. von SOBEE (Milchw. Zentbl., 6 (1910), No. 9, pp. 407–409).—The author discusses the comparative results obtained with the “neu-sal,” acid, and Rose-Gottlieb methods. He states that the “neu-sal” method is somewhat inconvenient to manipulate, and that he found some inaccuracies in the graduation of the apparatus.

In regard to O. von Sobee’s work with the “neu-sal” method, O. WENDELER (Milchw. Zentbl., 6 (1910), No. 10, pp. 711–713).—The author in reply to the above states that he is at a loss to understand O. von Sobee’s findings, especially in view of the fact that other workers report favorably on the method.

Estimation of the fat content of butter by the “sal” method, HESSE (Milch Ztg., 39 (1910), No. 38, pp. 440, 450).—Comparative tests were conducted between the Funke shaking out and the Rose-Gottlieb methods, and the “sal” method (E. S. R., p. 1134). The “sal” method was found to be rapid and on a par with the shaking out method, and the author concludes that it can be recommended for the analysis of butter.

The examination of cream with the “sal” method, HESSE (Milch Ztg., 39 (1910), No. 42, pp. 495, 496).—A comparative test between the “sal” Rose-Gottlieb, Spritz, and dilution methods is reported. It is noted that the “sal” method yields results which are from 0.4 to 0.5 per cent lower than those obtained by any of the gravimetric methods. A few notes in regard to manipulating it are given.

Estimation of fat in buttermilk, M. SIEGFELD and M. KERSTEN (Molk. Ztg. [Hildesheim], 24 (1910), No. 48, pp. 903, 904).—The authors cite the various

*Milch Ztg., 36 (1907), No. 50, p. 592.*
causes for the low results in estimating the fat in buttermilk, and report tests made to determine how the fat content estimated in the dairy agrees with that estimated in the laboratory by the Gerber method and the true fat content as estimated by the Rose-Gottlieb method.

It is seen from the results that centrifuging for 6 minutes gives practically the same results as found in the dairy and with the Gerber method, but in order to obtain correct results centrifuging for a period varying from 12 to 36 minutes was necessary. By a series of further tests the authors showed that the formation of plugs could be prevented by cooling the milk before adding the sulphuric acid.

Comparative tests with the various methods of fat estimation in buffalo's milk, F. Baintner and K. Irk (Kisérlet. Közlem., 13 (1910), No. 3, pp. 331-343).—The methods considered were the Soxhlet, Adams, Liebermann-Szekely, Rose-Gottlieb, Gerber's acidobutyrometric, Gerber’s “sal”, and Sichler's “sin-acid.”

The Soxhlet, Liebermann-Szekely, and improved Rose-Gottlieb methods are considered the most reliable and give good comparative results. The Liebermann-Szekely method gives comparative results only when the volume percentage obtained by this method is compared with the Soxhlet percentage by weight. Gerber's acidobutyrometric method, using dilutions of 50 per cent, gives about the same results as obtained by the Soxhlet method, but in some instances slightly lower. The Gerber “sal” method and Sichler's “sin-acid” method are of no value in ordinary dairy practice.

A comparative test between Gerber's (Lobeck's) and Funke's catalase testers, Hesse (Molk. Ztg. Berlin, 21 (1911), Nos. 1, pp. 1, 2; 2, pp. 13, 14).—It was found that Funke's apparatus yields slightly lower results than Lobeck's (E. S. R., 23, p. 13). It was also noted that slight errors were introduced by dissolved gases present in the milk, but that these could be overlooked when recording the results. Funke's apparatus has the advantage of being cleaned more easily. Recommendations are made for conducting the tests more uniformly.

Improvement of the Wiley method for determining the melting points of fats, H. Steenbock (Jour. Indus. and Engin. Chem., 2 (1910), No. 11, p. 380; abs. in Chem. Abs., 5 (1911), No. 1, p. 220).—By dropping the melted fat upon cold mercury from a proper height and with a good control of temperature, disks of good shape can be obtained. When cooled the disks are removed to a beaker containing cold dilute 50 per cent alcohol, the beaker placed in a vacuum desiccator, and the air exhausted.

About honey and the judging of honey (Chem. Weekbl., 7 (1910), No. 28, pp. 629-648).—This work consists of 2 parts, the first by L. Van Giersbergen on the characteristics and external judging of honey, and the second by G. L. Voerman on the judging of honey by chemical analysis.

Identification and determination of the protein substance in honey, E. Moreau (Ann. Falsif., 4 (1911), No. 27, pp. 36-41).—A discussion and description of methods.

In regard to estimating the shell content of cocoa, F. Filsinger and W. Bötticher (Ztschr. Öffentl. Chem., 16 (1910), No. 23, pp. 467, 468).—A reply to the criticism of Goske (E. S. R., 25, p. 206).

The significance of the acidity in judging foods and condiments, Lock (Ztschr. Öffentl. Chem., 16 (1910), No. 17, pp. 330-336).—The significance of the acidity of fats, oils, sausages, etc., in interpreting the analytical results is discussed.

various substances, e.g., glycine and hippuric acid, were tested with the process. "In most cases Kjeldahl's original process (use of potassium permanganate) is recommended; in such cases where there is danger of formation of piperidin rings the Gunning modification (use of potassium sulphate) is more appropriate."

Determination of nitrates in water by a sulphosalicylic acid reaction, H. Caron and D. Raquet (Bull. Soc. Chim. France, 4. ser., 7 (1910), No. 23, pp. 1025-1027).—The authors point out that with reagents composed of 1 per cent salicylic acid (or salicylate of soda) in sulphuric acid, and ammonia, there is a test for detecting nitrates and nitrate derivatives in water as sensitive as the Grandval and Lajoux phenol-sulphuric acid test.

A bacteriological method for determining available organic nitrogen, J. M. McCandless and F. C. Atkinson (Jour. Indus. and Engin. Chem., 3 (1911), No. 3, pp. 177, 178).—The method used was as follows:

- One gm. of cottonseed meal and 2 gm. of nitrolene or ammolene (leather fertilizers) containing 5.2, 9.4, and 3.42 per cent of total nitrogen, respectively, calculated as ammonia, were leached out with hot water. The cottonseed meal contained 0.73 per cent of water-soluble nitrogen, the nitrolene 5.34, and the ammolene 1.61 per cent, and aliquot parts of the solution were shaken with known amounts of soil. The filtrates from the mixture were placed in an incubator for 210 hours at a temperature of from 38 to 40° C., and under aerobic and anaerobic conditions.

- The anaerobic samples showed no nitrate or nitrite formation. The aerobic tests with ammolene showed a conversion of nearly 100 per cent of the water-soluble nitrogen to ammonia, while with nitrolene only about 63 per cent was converted. Cottonseed meal had a conversion of 30 per cent.

- The soils were furthermore shaken up with a solution containing 1 gm. of potassium phosphate, 2 gm. of sodium chlorid, 0.5 gm. of magnesium sulphate, and 0.05 gm. of calcium chlorid, and 50 cc. of the filtrate, along with the residues remaining on the filter paper, was incubated for 26 days. The results showed a solution of the nitrogenous substances corresponding to 74.9, 70.9, and 82.5 per cent, respectively.

- It is apparent from this work that the bacteria must first convert the insoluble proteins into soluble products and then into ammonia.

The determination of the amid nitrogen in proteins, W. Denis (Jour. Biol. Chem., 8 (1910), No. 5, pp. 427-435).—The author utilized the principle of the Folin method for estimating the ammonia in a mixture with amino acids resulting from the acid hydrolysis of proteins, e.g., edestin, casein, gelatin, and wool.

Substances rich in cystin yield less ammonia by this method than by the magnesia method. The procedure does not seem to interfere to any extent

---

with the subsequent determination of mono- and diamino nitrogen by the Hausmann method as modified by Osborne (E. S. R., 15, p. 221).

A colorimetric method for determining phosphoric acid, N. Passerini (Atti R. Accad. Econ. Agr. Georg. Firenze, 5, ser., 7 (1910), No. 3, pp. 239-253).—The method is based on the production of a yellow color by phosphomolybdic and gallic acids. Tests of soils with the method are given and compared with the usual molybdate method.

In regard to the determination of phosphorus in milk, E. Fleurent and L. Levi (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 15, p. 1015).—A polemical discussion in regard to the methods previously described (E. S. R., 25, pp. 312, 411). The authors show that the loss in the case of the organic phosphorus must not be ignored, as this is often as high as 21.3 per cent of the total organic phosphorus present in milk.

Electrolysis of humus solutions.—An improved method for the estimation of humus, J. B. Rather (Texas Sta. Bul. 139, pp. 15).—Following a suggestion made by Fraps and Hamner in a bulletin previously noted (E. S. R., 24, p. 302), in regard to the possibility of utilizing the electric current for removing suspended clay from soil solutions, the author as a result of his work concludes that “electrolysis removed most of the suspended clay from humus solutions and precipitated some of the humus. Electrolysis removed more clay than the Mooers and Hampton method. Electrolysis precipitated more clay than 1 gm. per liter of ammonium chlorid, but less than 2 gm. per liter of the salt. After precipitating the clay with 1 gm. per liter of ammonium chlorid the current used did not complete the precipitation of the clay. The presence of the salts interfere with the precipitation. Nitric nitrogen was formed by the current in the presence of free ammonia. Only a small amount of humus was precipitated by the current in the presence of 1 gm. per liter of ammonium chlorid, much less than by hydrochloric acid. In the absence of ammonium chlorid about a third of the humus was precipitated. All of the humus was not precipitated by hydrochloric acid. Humus and clay are precipitated from a neutral solution by the current. The electrolysis can not be used as a quantitative method for removal of clay or of estimation of humus.”

Some further work on other methods of removing clay revealed that “evaporation and solution does not remove the clay completely. Clay in humus solutions may be precipitated by ammonium carbonate or carbon dioxide, and the precipitant disappears on evaporating and drying the residue. Precipitation of the clay with ammonium carbonate is more nearly complete than by evaporation and solution and is a much shorter method.”

A brief bibliography is appended.

Detection and determination of small quantities of ethyl and methyl alcohol and of formic acid, R. F. Bacon (U. S. Dept. Agr., Bur. Chem. Circ. 74, pp. 8).—After discussing the amount of alcohol usually present in decomposed foods and the limitations of existing methods for determining the amount of alcohol in such foods, the author reports experiments which show that very small quantities of ethyl alcohol may be concentrated from salt solutions to a strength (from 2 to 4 per cent) at which they can be used for determining the amount of alcohol accurately by existing methods.

The author also studied the Vorisek method (E. S. R., 21, p. 705) for methyl alcohol in regard to its delicacy, and finally decided on the following method: “To 100 cc. of aqueous methyl alcohol in a 200 cc. distilling flask add from 5 to 8 gm. of chronic acid; collect 10 cc. of distillate and test for formaldehyde by the Leach or Hehner methods. If other oxidizable substances, such as acids, sugars, starches, proteids, etc., are present the solution under examination is exactly neutralized with sodium hydroxid and one-third of it is distilled, the
distillate being oxidized and redistilled as has just been described. The use of the relatively large quantity of chromic acid indicated is found to increase the delicacy of the reaction. By the proposed method it is very easy to detect one part of methyl alcohol in 100,000 parts of water, and by making one preliminary distillation to concentrate the methyl alcohol, collecting the first 100 cc. from a liter and then proceeding as before described, a very strong test was obtained from a solution containing only one part of methyl alcohol per million.

"When testing for methyl alcohol in the presence of strong ethyl alcohol it is advisable to dilute the alcohol with water to obtain approximately a 20 per cent solution, as otherwise the action of the chromic acid on the ethyl alcohol may become explosively violent."

With the modified method it is possible to detect 0.1 per cent of methyl alcohol in 80 per cent ethyl alcohol, and with fractionation 0.01 per cent.

As formic acid is becoming of importance in regard to food products, the author studied its reduction with various substances, particularly as regards sensitiveness. The substances tried for this purpose were magnesium filings, metallic calcium, coppered zinc filings, coppered zinc dust, zinc amalgam, coppered aluminum, 1 per cent sodium amalgam, 1 per cent sodium amalgam with magnesium chlorid solution, aluminum, aluminum amalgam, zinc dust, and zinc filings. With a 1 per cent solution of formic acid the first 4 substances gave a positive reduction, the 5 following a negative result, and the 3 last only faint evidences of reduction. With 0.1 per cent solution of formic acid the first 4 substances mentioned gave a positive reduction. All things considered, magnesium filings seemed to give the best results, and form the basis of a qualitative method which is given.

The quantitative estimation of formic acid is accomplished as follows: "Distill the solution containing the formic acid with a small quantity of phosphoric acid until the distillate is no longer acid. If the volume of this distillate is too large to be conveniently handled, neutralize it with sodium hydroxid and evaporate to a convenient volume. Add an excess of platinit chlorid and sufficient acetic acid to make the solution strongly acid (usually about 1 or 2 cc. of glacial acetic acid for less than 1 gm. of formic acid), and boil the solution for 1 hour, using a reflux condenser. Collect the reduced platinum in the usual manner and weigh. The weight of the platinum multiplied by 0.472 equals the formic acid present."

The possibility of using the electrical conductivity method for this purpose is suggested.

Positive results were obtained with methyl, ethyl, propyl, isobutyl, allyl, and benzylc alcohols, santalol, and amylene hydrate. With allyl alcohol the coloration obtained was orange, and with ethylene glycol after ½ hour faintly red, becoming more intense 5 minutes later. With glycerin the reaction appeared only after ½ hour. When no alcohol at all was employed a faint red coloration was obtained after ½ hour, which later became much more intense.

The determination of arsenic in insecticides, E. B. Holland (Jour. Indus. and Engin. Chem., 3 (1911), No. 3, pp. 165-171).—This is a study of methods.

The author at first adopted Thatcher's suggestion for determining arsenious acid with the Mohr method, with particular regard to the ratio of the sample to be taken to the acetate solution (1:25). This was, however, found to be too small, and it was further noted that the practice of adding hydrochloric acid to
the sample after boiling with acetate for 5 minutes seemed to yield results which were very variable and generally low.

The method was finally modified as follows: “Transfer 2 gm. of finely pulv"erized sample together with 50 cc. of sodium acetate (1:2) to a 500 cc. graduated flask and boil 5 minutes. Cool under tap, add about 60 cc. of hydrochloric acid (1:3) and shake until solution is effected. Make to volume and filter. Pipette 25 or 50 cc. into an Erlenmeyer flask, neutralize with dry sodium bicarbonate, add 25 cc. of sodium potassium tartrate (1:10) to redissolve precipitated copper, approximately 3 gm. of sodium bicarbonate, water sufficient to make a volume of 100 cc., 2 cc. starch paste (1:200), and titrate with normal-twentieth iodin to a permanent blue color. Toward the end of the reaction cork the flask and shake vigorously to insure proper end-point. Calculate results as arsenious oxid. The residue in the graduated flask is brought onto the filter, well washed, calcined in a porcelain crucible, and weighed as insoluble matter.”

The process, according to the author, yields excellent results when used for copper aceto-arsonite, copper arsenite, and calcium arsenite. For determining arsenic acid the author investigated the Gooch-Browning-Haywood process (E. S. R., 19, p. 310), and modified this as follows: “Transfer 2 gm. of the finely ground sample together with 60 cc. of nitric acid (1:3) to a 500 cc. graduated flask, bring to boil, cool, make to volume, and filter. Pipette 50 or 100 cc. into a 150 cc. Jena Griffin beaker, add 10 cc. of sulphuric acid (2:1), evaporate, heat in an air bath at 150 to 200° C. to expel last traces of moisture, and then on asbestos board to the appearance of dense white fumes to insure complete removal of nitric acid. Add a small quantity of water, and when cold filter through a sugar tube under suction into a 300 cc. Erlenmeyer flask and wash to about 100 cc. Add 10 cc. of potassium iodid (165:1.000) and boil until free iodin is expelled—solution practically colorless—with the reduction of arsenic acid to arsenious acid: \(\text{As}_2\text{O}_3 + 4\text{I}^- = \text{As}_2\text{O}_5 + 4\text{H}^+ + 2\text{H}_2\text{O}\). Dilute, cool immediately, neutralize with sodium hydroxid, and render slightly acid with sulphuric acid. Add starch paste, and if any free iodin remains add dilute (normal-fiftieth) thiosulphate carefully with vigorous shaking to the absence of blue color: \(2\text{I}^- + 2\text{Na}_2\text{S}_2\text{O}_3 = \text{Na}_2\text{S}_2\text{O}_5 + 2\text{NaI}\). Add excess of sodium bicarbonate and titrate as usual with normal-twentieth iodin, reporting as arsenic oxid. The residue in the graduated flask is brought onto the filter, washed, calcined, and weighed as insoluble matter.”

Detection of dioxydiamidoarsenobenzol and its differentiation from inorganic arsenic in forensic cases, G. O. Gæbel (Arch. Pharm., 249 (1911), No. 1, pp. 49-56; abs. in Analyst, 36 (1911), No. 421, pp. 153, 154).—According to the author dioxydiamidoarsenobenzol, which contains 34 per cent of arsenic, gives the Reinsch, Marsh, and Gutzeit tests for arsenic, and it may also be detected by a biological test with Penicillium glaucum. It may, however, be distinguished from the inorganic form with Bettendorf’s reagent, which gives with it a yellow amorphous precipitate. The author also points out the readiness with which the organic complex in the molecule may be oxidized, and thus serve as a basis for several reactions.

[Miscellaneous analyses], E. F. Ladd (North Dakota Sta. Rpt. 1910, pp. 34-40).—Analyses are reported of cows’ and human milks, ammoniated lawn lime and other commercial fertilizer products, ground feed, a potato-bug killer, cement, clays, iron ore, sugar beets, and barley. Tests are also reported of the illuminating value of three samples of calcium carbid.

The problem of potato desiccation and its accomplishment by means of cooperation (Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Int., 2 (1911), No. 1, pp. 5-21).—This is a review of the work done in Germany on
potato drying. The various phases of the problem discussed are the technical process of desiccation, the products of potato desiccation and their utilization, result of experiments as to the food value of desiccated potatoes, rules for the trade in the products of potato desiccation, and the accomplishment of potato desiccation by means of cooperative societies.

Crop plants for paper making, C. J. Brand (U. S. Dept. Agr., Bur. Plant Indus. Circ. 82, pp. 19, figs. 3).—This is substantially a reprint from another source (E. S. R., 25, p. 507), but the circular itself is printed on papers made from some of the crop plants described.

**METEOROLOGY—WATER.**

Practical meteorology, D. J. Ricart y Giralt (Mem. R. Acad. Cien. y Artes Barcelona, 5, ser., 8 (1910), No. 11, pp. 13).—This article discusses various ways in which meteorological observations are being made of practical utility for navigation, agriculture, and health.

Meteorology, E. Kleinschmidt (Jahrb. Naturw., 26 (1910–11), pp. 122–123).—This is a review in the usual form of recent progress in various meteorological lines.

Agricultural meteorology (Rev. Sci. [Paris], 49 (1911), II, No. 3, pp. 85, 86; Rev. Vit., 86 (1911), No. 918, pp. 78–81).—Reference is here made to a report of a committee authorized by the French parliament to investigate and report upon a plan of organization of a general service for agricultural meteorology in France.

[Meteorological observations], E. F. Ladd (North Dakota Stu. Rpt. 1909, pp. 18–30).—Summaries are given in the usual form of observations during 1909 on temperature, rainfall, sunshine, wind velocity, and evaporation from a water surface.

On the theory of precipitation, V. Láska (Sitzber. K. Böhm. Gesell. Wiss. Math. Naturw. Cl., 1910, Art. XV, pp. 7, figs. 4).—This is a continuation of the studies previously noted (E. S. R., 25, p. 508), applying a method of calculating rainfall extremes from means and quotients of variation to data reported by Hellmann.

On the electricity of rain and its origin in thunderstorms, G. C. Simpson (Mem. Indian Met. Dept., 29 (1910), pt. 8, pp. 141–332, pls. 2; rev. in Nature [London], 85 (1910), No. 2142, pp. 80, 81).—This paper records the results of measurements of electricity brought down by rain, and laboratory studies of the physical process by which electrical separation takes place during thunderstorms, and advances a new theory regarding the relation of electricity to the formation and breaking up of raindrops during thunderstorms. This theory is that there are normally present in thunderstorm areas upward currents of air of sufficient velocity to prevent the falling of raindrops and to cause a continuous cycle of “growth, breaking up (with separation of electricity), fresh growth, and so on, at a nearly constant height in the atmosphere until the charge is so great as to produce at a certain level a gradient larger than 30,000 volts per centimeter, which [is taken] to be the electric strength of air. When this limit is reached, a lightning flash neutralizes the accumulated charge over a limited area, and the process goes on repeating itself.”

The influence of climatic factors on plant growth in general and particularly upon the yield of plants, P. Vageler (Tropenpflanzer, 15 (1911), No. 6, pp. 289–302).—The influence of heat, light, and moisture upon the growth of plants, with particular reference to tropical conditions is discussed.

Agr. Intel. and Plant Diseases, 1911, No. 3, p. 503).—This is a discussion of various means of preventing or mitigating the effects of frosts, wet and dry spells, and excessive snowfall.

The constitution of water, J. Duclaux (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 21, pp. 1387-1390).—This article deals with certain anomalies in the physical properties of water, particularly the increase of volume at the freezing point. This phenomenon is attributed to polymerization.

Progress in the chemistry of water, C. Blachier (Chem. Ztg., 35 (1911), Nos. 40, pp. 353-354; 41, pp. 370-372; 43, pp. 390-392; 44, pp. 398, 399).—This is a critical review of the more recent investigations on the constitution of water, water analysis, judging water, behavior of water in steam boilers, purification of water, and metallic corrosion by water.

The chemical composition and biological properties of water, J. König, J. Kuhlmann, and A. Thienemann (Landw. Jahrb., 40 (1911), No. 3-4, pp. 409-474, pls. 1, figs. 7).—This article reports studies of the effect on the physical and chemical properties and on the natural flora and fauna of water of the addition of various inorganic and organic substances. There was found to be a relation between the chemical composition and biological properties of water, and it is concluded, therefore, that both chemical and biological examinations are necessary in judging as to contamination.

Ground water level and cultivation, M. Ringelmann (Jour. Agr. Prat., u. scr., 21 (1911), No. 17, pp. 525-528, figs. 3).—This article discusses the inclination and depth of the water table in relation to plant growth and to methods of cultivating, draining, and irrigating the soil.

Wells, M. Ringelmann (Jour. Agr. Prat., u. scr., 21 (1911), Nos. 19, pp. 595-597, figs. 3; 20, pp. 623-625, figs. 2; 21, pp. 656, 657, figs. 3; 23, pp. 723-726, figs. 2; 24, pp. 752, 753, figs. 3; 25, pp. 782-784, figs. 2).—In continuation of previous articles on the construction of wells, the author gives information regarding the lining and curbing of wells, and discusses the feeding (maintenance of the water supply) of wells, ventilation of wells, temperature of water in wells, composition of waters from different geological formations, and contamination of wells.

Surface water supply of the Lower Mississippi basin, 1909, W. B. Freeman and R. H. Bolster (U. S. Geol. Survey, Water-Supply Paper No. 267, pp. 99, pls. 2, fig. 1).—This is a report of measurements of flow of water in this area, including the drainage basins of the White, Arkansas, and Yazoo rivers.

Surface water supply of the western Gulf of Mexico, 1909, W. B. Freeman and R. H. Bolster (U. S. Geol. Survey, Water-Supply Paper No. 268, pp. 107, pls. 6).—This is a report of measurements of flow of water in this area, including the Rio Grande drainage basin.

Geology and underground waters of northeastern Texas, C. H. Gordon (U. S. Geol. Survey, Water-Supply Paper No. 276, pp. 78, pls. 2, figs. 6).—This is a report of a study of underground waters of an area of 5,980 square miles, comprising the counties of Bowie, Red River, Lamar, Delta, Hopkins, Franklin, Titus, Morris, Camp, and Cass. The geography, physiography, and geology of the region are also briefly discussed.

This is "a report on the water resources of an important section of central Utah, including a discussion of rainfall, soil, vegetation, streams, and industrial development. The occurrence of ground water is described and its quality considered. Its availability for irrigation, culinary supplies, and boiler supplies is given special attention. Watering places on routes of travel in the vicinity of the Sevier Desert are listed, and the report concludes with detailed descriptions of the water resources of the region."

Quality of the water supplies of Kansas, H. N. Parker (U. S. Geol. Survey, Water-Supply Paper No. 273, pp. 9-348, pl. 1).—This paper reports the results of an investigation, conducted in cooperation with the Kansas State Board of Health, to determine the quality of the water supplies of the State. It describes briefly the salient geological features in order that their relation to the water supply may be understood and contains 185 tables, giving analyses of the different waters. The underground sources are discussed separately, by counties, and the surface streams by river basins.

Preliminary report on stream pollution by mine waters in southeastern Kansas, E. H. S. Bailey (U. S. Geol. Survey, Water-Supply Paper No. 273, pp. 349-361, fig. 1).—Analyses of waters from lead, zinc, and coal mines and from concentration mills, as well as some studies of the effects of such waters on fish and on metals are reported.

Denitrifying bacteria of percolating beds, Lemoigne (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 26, pp. 1873-1875; abs. in Recr. Sci. [Paris], 49 (1911), II, No. 2, p. 61).—Various organisms occurring in percolating beds were isolated and studied. Among these were found several which rapidly destroyed nitric acid. Two species appeared to be particularly abundant, Bacillus subtilis and a closely allied species. It was found that aeration favored denitrification with these bacteria, which were not able to utilize the oxygen of nitrates for their respiration.

The purification of sewage by the soil and by bacterial beds, A. Müntz and E. Lainé (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 19, pp. 1204-1208; abs. in Recr. Sci. [Paris], 49 (1911), I, No. 20, p. 635; Jour. Chem. Soc. [London], 100 (1911), No. 585, II, p. 639; Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intell. and Plant Diseases, 1911, No. 5, pp. 1029, 1030).—In the experiments here reported, which were a continuation of those previously noted (E. S. R., 22, p. 421), destruction of organic matter by oxidation with loss of gaseous nitrogen was much less and nitrification was more rapid in the soil than in artificial bacterial beds. In these experiments the loss of nitrogen from sewage was 16.36 per cent during purification by soil and 60 per cent in septic tanks.

The agricultural use of sewage, A. Müntz and E. Lainé (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 26, pp. 1814-1818; abs. in Recr. Sci. [Paris], 49 (1911), II, No. 2, p. 59; Recr. Gén. Agron., n. sér., 6 (1911), No. 6-7, pp. 241-245).—Attention is called to the fact that the use of sewage for irrigation not only results in its purification but also serves a useful purpose in supplying water and fertilizer to the soil. The authors studied not only the amount of fertilizing matter carried by sewage but also the best amounts of sewage to use for irrigation on different soils and crops. They reached the conclusion that if the sewage waters of Paris could be carried to agricultural areas of sufficient
size they could be made to fertilize an area from 10 to 15 times that on which they are now actually used.

A study of sewage from the point of view of purification and utilization in agriculture, A. Münz and E. Laimé (Ann. Inst. Nat. Agron., 2, ser., 10 (1911), No. 1, pp. 5-48).—This is a more detailed account of the investigations noted above.

SOILS—FERTILIZERS.

Studies on soil physics, W. H. Green and G. A. Ampt (Jour. Agr. Sci., 4 (1911), No. 1, pp. 1-24, figs. 5; abs. in Jour. Soc. Chem. Indus., 30 (1911), No. 12, p. 759).—This paper defines and attempts to construct a scientific basis for three fundamental soil constants, (1) the specific pore or interstitial space, (2) permeability to water, as well as permeability to air, and (3) capillarity coefficient, and describes methods and apparatus used for their measurement, with results obtained with 3 types of soil—clay, loam, and sand.

"The specific pore or interstitial space [is] defined as the free space per unit volume of soil.

"The permeability to water [is] measured by that volume of water which will pass per second through a soil column of unit length and of unit area of cross section when under 1 cm. head of water pressure. The permeability to air may be similarly defined.

"The capillarity coefficient [is] defined as the tension due to capillary forces per unit area of cross section of the pore spaces which tends to draw the water from the saturated to the dry region of the soil."

The moisture content affected strongly the pore space and permeability of the soils. Permeability was dependent upon the average pore space, and was influenced also by the system of arrangement of the soil particles. The soils differed markedly in their constants, as was illustrated by the wide ratio between the permeability of clay soils for water and of air, indicating that the water has the effect of swelling out the colloidal matter in the soil, thus constricting the capillary passages.
The authors deduce formulas connecting the movements of air and water with the soil constants, and suggest that such measurement of pore space, permeability, and capillarity "is of more importance than, and should replace, the determination of the sizes of soil particles as in the usual 'mechanical analysis' of soils."

The determination of the absorptive capacity of soils by the Knop method, M. A. Eoony (Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 12 (1911), No. 3, pp. 349-356).—This article reports the results of experiments to test the effect of antiseptics, chloroform, and of the length of standing on the absorption coefficient of soils.

The conclusions reached are that (1) with the antiseptics the length of standing had no effect on the absorption coefficient; (2) the absorptive capacity of the soils was, in general, higher without the chloroform than with it; (3) different soils without the antiseptics varied in their absorptive capacity for a given length of time, the absorption coefficient of chernozem and loess soils decreasing and of podzol soils increasing on standing.

A comparison of the effect of different antiseptics showed that toluiol gave the best results. Chloroform and thymol did not completely inhibit bacterial activity, and the latter increased the absorption coefficient.

The author suggests that antiseptics be used in connection with the usual Knop method of determining the absorptive capacity of soils, inasmuch as soil samples are usually taken under dissimilar conditions which cause variations in the microflora and therefore in the absorption coefficient.
The moisture of typical semiarid and alkali soils in relation to their stage of formation, S. K. Chaianov (Zhur. Opytn. Agron. (Russ. Jour. Exppt. Landv.), 12 (1911), No. 3, pp. 321-348, figs. 6).—This article reports the results of observations during 1908, 1909, and 1910 on the moisture of a virgin soil. The work is divided into a description of the morphology, chemical and physical composition, and flora of the soil, and determinations of the moisture, soluble salts, and carbon dioxide of loam and alkali soils at different depths and seasons of the year.

It was found that all changes in moisture of alkali soils occurred in the upper layers, not exceeding a depth of 25 cm. (9.85 in.). The water almost never penetrated beyond these layers.

The moisture of typical semiarid soils varied to a depth of 150 cm. (59.1 in.). There was a pronounced increase in depth of penetration of moisture in spring, and it extended still deeper in summer. During dry years the moisture of typical semiarid and alkali soils was substantially the same, the former being slightly more moist in spring. The moisture content and permeability of alkali soils are determined by the characteristics of the 25 to 35 cm. (9.85 to 13.79 in.) layers.

The salt content of semiarid loam soils may be decreased by the movement of water in the soil, whereas the salt content of alkali soils continually increases.

Carbon dioxide in ground air, G. I. Joukow (Khozishtvo, 6, (1911), No. 2, pp. 37-56; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 1911, No. 3, pp. 510, 511).—From a study of factors influencing the carbon dioxide of soil air the following conclusions were reached:

“Fallow soils treated with dry-farming methods of frequent cultivation, in order to maintain moisture and a high temperature in the soil, contain more carbon dioxide than those less cultivated. In April fallows the content of carbon dioxide increases during summer and reaches a maximum in August. This content varies according to depth between a maximum at 30 cm. and a minimum at 10 cm. Farmyard manure increases the content of carbon dioxide in the soil. . . . Carbon dioxide accumulates in greater quantity in the air of soils where lucerne, beets, clover, and potatoes are grown than in uncultivated soils. Sandy soils are much less rich in carbon dioxide than those containing organic matter, especially peaty soils.”

On carbon dioxide in ground air, A. Suprunenko (Zap. Novo-Alexsandri. Inst. Selsk. Khoz. i Lisov., 21 (1910), No. 1, pp. 59-63; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 1911, No. 3, pp. 511, 512).—The author concludes from his investigations that “the quantity of carbon dioxide contained in the air of the soil is never enough to injure vegetation; it varies according to the nature of the soil. . . . The content of carbon dioxide in proportion to the depth can only be ascertained on fallow soils, the position and development of roots in cultivated soils causing irregularities. . . . Light rains after a long period of drought increase the carbon dioxide in soils, which shows that they awaken the activity of plants and micro-organisms. Abundant rains produce a contrary effect.”

The production of plant food in the soil, E. J. Russell (Jour. Roy. Agr. Soc. England, 71 (1910), pp. 9-26, figs. 7).—This article is based upon investigations on the effect of partial sterilization of soils already noted (E. S. R., 22, p. 121), and upon observations as to the growth of various crops in untreated and partially sterilized soils in pots.

The increased productiveness observed in the partially sterilized soils is ascribed, as in previous papers, primarily to the increased production of ammonia in the treated soils, and this in turn to the destruction by partial steriliza-
tion of the soil organisms which interfere with the activity of the ammonia-forming bacteria.

Experiments on ammonia and nitrate formation in soils, II, J. G. Lipman, P. E. Brown, and I. L. Owen (Centbl. Bakt. [etc.], 2, Abt., 39 (1911), No. 7-12; pp. 156-181; abs. in Jour. Chem. Soc. [London], 100 (1911), No. 555, II, pp. 649, 650).—This is a second communication on this subject (E. S. R., 23, p. 621), and deals with ammonia formation from dried blood as affected by the mechanical composition of the soil, the amount of moisture and lime present, and various chemical and physical factors.

It was found that there were considerable losses of ammonia from well aerated soils, that ammonia formation was to a large extent controlled by the moisture content of the soil, that smaller applications of calcium carbonate stimulated ammonification but that larger additions depressed it, and, in general, that the rate of ammonification was controlled by a number of chemical and physical soil factors.

The authors conclude that the method of measurement of ammonia formation may be used with success "for the study of a great variety of soil problems that concern the formation and transformation of soil humus, and, even more generally, of many problems that belong properly within the domain of soil fertility and plant nutrition."

The method employed was in brief as follows: "In all cases 100 gm. of material was employed. Water was added in amounts sufficient to create optimum moisture conditions; but because of the differences in the water holding power of the different ingredients 18 per cent of moisture was allowed for the soil itself, 12 per cent for the sand, and 60 per cent for the dried blood. In each case the soil, or the mixture of soil and sand, was placed in a tumbler; the required amount of dried blood added and thoroughly mixed with the soil, and the material was then moistened, the quantities of water added including the 6 cc. of fresh soil infusion employed in each case to provide abundant and uniform inoculation. The tumblers were covered with a Petri dish cover and kept in the incubator at 27 to 28° C. for seven days; at the end of that time the ammonia was distilled off into standard hydrochloric acid and the distillate titrated against standard ammonia."

The chemical nature of the organic nitrogen in the soil, S. L. Jodidi (Iowa Sta. Research Bul. 1, pp. 3-46, fig. 1).—A study of the organic nitrogenous substances in plats of Wisconsin drift soil treated in different ways similar to that on nitrogenous compounds in peat soils (E. S. R., 22, p. 618) is reported in detail in this bulletin. The same methods were employed in this investigation as in the earlier work, viz, those used by Hausmann and Osborne in protein chemistry. The plan of investigation was based upon the idea that soil organic matter or humus is a resultant of the decomposition of plants all of which contain a large if not a predominant proportion of nitrogen in the form of protein, and that in the decomposition of the protein there are formed (1) albumoses, (2) peptones (polypeptides), (3) amino acids and acid amid, (4) ammonia, (5) nitrites, and (6) nitrates.

The general method of procedure in separating the organic nitrogenous substances was to evaporate the hydrochloric acid extract of the soil practically to dryness and distill it with cream of magnesia, the ammonia obtained by this process representing the amid in the soil. The residue from the distillation with magnesia was extracted with water and the extract, after acidulating with sulphuric acid, was treated with phosphotungstic acid. The precipitate thus obtained contained the diamino acids and the filtrate from this precipitate represented the monamino acids. It was found that by these methods the bulk of
the nitrogen present in the soil can be extracted and then separated into various groups of definite composition.

"The amount of total nitrogen extracted from the soil of the various plats examined, by boiling with hydrochloric acid, was on the average 75.83 per cent (from 71.12 to 81.2 per cent), the balance (from 28.88 to 18.8 per cent) having remained undissolved.

"The acid-soluble nitrogen is made up as follows: Ammoniacal nitrogen, from 1.22 to 1.97 per cent (from 0.99 to 1.14 per cent of the total soil nitrogen); nitric nitrogen, from 0.07 to 1.46 per cent (from 0.05 to 1.14 per cent of the total soil nitrogen); nitrogen of acid amids, from 25.23 to 33.03 per cent; nitrogen of diamino acids from 11.61 to 13 per cent; nitrogen of monamino acids from 22.2 to 55.66 per cent. The rest of the organic nitrogen consists of compounds other than acid amids and amino acids.

"By boiling with water, only a small proportion of nitrogen, namely from 2.92 to 9.96 per cent of total soil nitrogen, could be extracted from the various soils investigated. This, taken together with the fact that the bulk of the soil nitrogen is made up of acid amids and amino acids all of which are fairly soluble in water, makes it very likely that these compounds are present in the soil not in a free state, but in some kind of combination."

It was observed in plats which had received the more recent applications of organic manures that, with the exception of from 8 to 12 per cent, the organic nitrogen consisted of acid amids, diamino acids, and monamino acids, but in plats which had not been recently manured a considerable percentage, from 47 to 60 per cent, of compounds belonging to other classes than acid amids and amino acids were found.

"Since we have found that the organic nitrogenous compounds in Iowa soils as well as in Michigan peat soils are made up chiefly of acid amids and amino acids, despite a considerable variety of the sources of the organic nitrogen, it seems fairly safe to state that the bulk of the organic nitrogen in the majority of soils, if not in all, consists very likely of acid amids and amino acids."

The chemical nature of the organic nitrogen in the soil, S. L. Jondi (Jour. Amer. Chem. Soc., 33 (1911), No. 7, pp. 1226-1241; abs. in Chem. Abs., 5 (1911), No. 19, p. 3313).—This article presents the more strictly chemical phases of work more fully reported above.

Organic nitrogenous compounds in peat soils, II, C. S. Robinson (Michigan Sta. Tech. Bul. 7, pp. 22, figs. 2).—This is a continuation of work previously noted (E. S. R., 22, p. 618), reviewing the results of investigations on the composition of the organic matter of peat soils and dealing particularly with 2 compounds, leucin and isoleucin, which were isolated from such soils in considerable quantities.

"The work reported in this paper and that done by Suzuki proves quite conclusively that a considerable portion of the nitrogen is present in the form of a protein compound or a mixture of such compounds which can be broken down on treatment with acids in the same manner as casein, egg albumin, etc. In the samples of peat studied for this work about 26 per cent of the total nitrogen was combined in this form in such a way that it could be converted by hydrolysis into primary amins, probably with the formation of amino acids. About 10 per cent of the total nitrogen is due to the presence of acid amids. From the work of Schreiner and Shorey purin, pyrimdin and pyridin compounds constitute a part of the remainder. The greater part is, however, present in forms concerning which we know nothing and which may represent the most important factors in aiding or inhibiting plant growth. It seems probable, from the work done so far, that the classes of compounds constituting
The greatest need at present in determining the value of the organic nitrogenous material of peat and humus is a closer knowledge of the individual substances actually present in such material and those which may possibly be formed by natural agents in the soil."

Biochemical relations of the phosphate ion in the soil, J. Stoklasa (Centbl. Bakf. [etc.], 2. Abt., 29 (1911), No. 13–19, pp. 355–515, pls. 2; abs. in Jour. Chem. Soc. [London], 100 (1911), No. 583, II, p. 529; Centbl. Agr. Chem., 70 (1911), No. 9, pp. 777–535).—This article deals primarily with the inorganic phosphates of soils and with the conditions under which they become soluble in water, especially the part played by micro-organisms in the transformation of the phosphates. It is shown, however, that there is a considerable proportion of organic phosphorus in fertile soils in form of phosphatids, phytins, and nucleoproteids.

The insoluble phosphates are rendered soluble and available as plant food mainly by the action of carbon dioxid and organic acids produced by the micro-organisms of the soil. Bacterial activity is measured by the amount of carbon dioxid contained in the soil, and this varies widely with the physical and chemical conditions of the soil as well as its bacterial content.

Data are given showing the variation in rate of production of carbon dioxid by different kinds of soil organisms, and from these data it is estimated that under the conditions of these experiments soil organisms produced carbon dioxid at the rate of 75 kg. per hectare (66.75 lbs. per acre) to a depth of 40 cm. (15.76 in.) per day, besides other organic acids which dissolve phosphates and furnish food for the organisms.

The author holds that the cooperation which exists between autotrophic and heterotrophic organisms in the soil is not entirely explained by the death of the former providing the latter with assimilable carbohydrates. The autotrophic organisms always contain phosphatids from which the heterotrophic organisms obtain phosphorus in readily assimilable form.

The process of assimilation of phosphate by bacteria and its conversion by them into organic compounds is called by the author biological absorption of phosphoric acid in the soil. The intensity of this process varied greatly with the bacterial content of the soil, 98 per cent of phosphoric acid anhydrid being absorbed by an inoculated soil as compared with 60 per cent for an uninoculated soil. The biological absorptive capacity of the soil was closely related to the vegetative growth, and hence may be taken as an important factor in determining the productivity of a soil. Of the phosphoric acid anhydrid of sterilized soils from 40 to 52 per cent was absorbed as compared with from 60 to 92 per cent for soils not sterilized. From 2 to 2.3 gm. of free nitrogen was assimilated by Azotobacter per gram of phosphoric acid anhydrid. The addition of dipotassium phosphate greatly stimulated the development of bacteria in rather unproductive soils, thereby increasing the nitrogen content of the soil. In addition to increasing the nitrogen of the soil, appreciable quantities of easily assimilable mineral plant food, as the phosphate ions, were also made available by the action of the nitrogen-fixing bacteria of the soil. The amount of phosphoric acid anhydrid which was changed into organic phosphorus substances was larger with ammonifying bacteria than with Azotobacter.

The author found a definite relation between the assimilation of free nitrogen and the carbon and phosphoric acid contents of the soil. With nutrient solutions containing no phosphoric acid the bacterial growth was reduced to a minimum and the production of dry matter reduced to a point where its determination was impossible.

It thus appears that one of the principle functions of phosphorus in the soil is to aid in the promotion of bacterial action.
Phosphoric acid in relation to Australian soils and vegetation, T. Cherry (Jour. Dept. Agr. Victoria, 9 (1911), No. 2, pp. 71-74; abs. in Chem. Abs., 5 (1911), No. 13, pp. 2293, 2294).—This article reports the results of analyses of soils and of native plants of Victoria, and calls attention to their relatively low phosphoric acid content. Surface soils generally contain from 0.5 to 0.15 per cent phosphoric acid, the volcanic and alluvial soils over 0.15 per cent.

Analyses of a number of characteristic native plants of the region showed only one-tenth of the phosphoric acid content of cultivated cereals grown on the same soil. "It would therefore appear that the native plants have established a kind of equilibrium in phosphoric acid with the soil."

The author is of the opinion that the bone diseases which affect animals kept too long on "kangaroo grasses" and similar grazing country may be caused by the low phosphoric acid content of the plants.

Soils of the Eastern United States and their use, VIII-XVIII, J. A. Bonsteel. (U. S. Dept. Agr., Bur. Soils Circs. 30, pp. 15; 31, pp. 17; 32, pp. 18; 33, pp. 17; 34, pp. 15; 35, pp. 19; 36, pp. 16; 37, pp. 16; 38, pp. 17; 39, pp. 19; 40, pp. 15).—These circulars deal respectively with the following soil types as surveyed and mapped by the Bureau of Soils: Circular 30, The Clarksville Silt Loam, of which a total area of 1,599,938 acres in 15 different surveys in 5 States has been surveyed and mapped; Circular 31. The Miami Clay Loam, of which a total of 2,281,482 acres in 18 areas in 5 States has been surveyed and mapped; Circular 32, The Marshall Silt Loam, of which a total of 4,084,230 acres in 20 areas in 7 States has been surveyed and mapped; Circular 33, The Knox Silt Loam, of which a total of 1,881,024 acres in 17 areas in 7 States has been surveyed and mapped; Circular 34. The Carrington Loam, of which a total of 1,601,088 acres in 14 areas in 6 States has been surveyed and mapped; Circular 35, The Memphis Silt Loam, of which a total of 1,863,290 acres in 12 areas in 6 States has been surveyed and mapped; Circular 36, The Fargo Clay Loam, of which a total of 901,024 acres in 6 surveys in 3 States has been surveyed and mapped. Circular 37, The Clyde Loam, of which a total of 561,088 acres in 11 areas in 4 States has been surveyed and mapped; Circular 38, The Dekalb Silt Loam, of which a total of 1,122,914 acres in 19 areas in 8 States has been surveyed and mapped; Circular 39, The Porters Loam and Porters Black Loam, of the former of which a total of 436,160 acres in 4 areas in 2 States has been surveyed and mapped and of the latter 193,550 acres in 7 areas in 2 States; and Circular 40, The Wabash Silt Loam, of which a total area of 801,256 acres in 28 areas in 9 States has been surveyed and mapped.

[Biological survey at McLeod, North Dakota], W. B. Bell (North Dakota Stu. Rpt. 1909, pp. 57-62).—This report presents observations and recommendations based upon a biological survey at McLeod, N. Dak., as to the most profitable utilization of the large area of sandy soils of which the vicinity is typical. The soils are classified as (1) McLeod sand, (2) Fargo fine sand, (3) Fargo fine sandy loam, and (4) dune sand. It is considered that these soils are suitable for dairying, truck farming, and fruit growing, and suggestions are presented regarding each of these lines. The amount of rainfall at McLeod is shown to have been 8.24 in. from June 25 to September 1, 1909.

Soil analysis, E. F. Ladd (North Dakota Stu. Rpt. 1910, pp. 31-34).—Analyses of a number of samples of soils from 9 state demonstration farms as well as from other sources are reported.

Contribution to the study of molds, A. Mazzarone (Bul. R. Soc. Toscana Ort., 3. ser., 16 (1911), No. 1, pp. 14-23; abs. in Rev. Gén. Agron., 6 (1911), No. 5, pp. 193-195).—This article reports the results of physical and chemical analyses of heath, black, and different forest molds commonly used in Italy. The author divides the molds on the basis of their mineral and organic. 

12544°—No. 7—11.—3
matter content into (1) beech, heath, and black molds, and (2) forest molds. The beech, heath, and black molds were rich in mineral matter, but low in organic matter. The forest molds were low in nitrogen and phosphoric acid. There was substantially no difference in the moisture of the 2 classes of molds, but the forest molds had a higher retentive power for water.

The maintenance of soil fertility, C. E. Thorne (Quart. Rpt. Kans. Bd. Agr., 30 (1911), No. 117, pp. 92-106).—The author describes the methods of maintaining soil fertility employed at the Ohio Station, reaching the general conclusion “that in the present stage of the world’s development this end is to be attained most economically through the production of live stock and the systematic saving and utilization of the resulting waste products, both at the stable and at the slaughterhouse; supplementing these products from the deposits of the mineral stores of combined nitrogen, phosphorus, and potassium; keeping the soil sweet with lime; and so adjusting our system of cropping as to provide for the greatest possible use of the nitrogen-gathering crops.”

The feeding of crops and stock, A. D. Hall (London, 1911, pp. XVI+298, pls. 23, fig. 1).—This latest book by the director of the Rothamsted Experimental Station is described as an introduction to the science of the nutrition of plants and animals, which is intended “to give the student of agriculture a general framework of ideas before he enters upon the more detailed study of agricultural chemistry,” and thus enable him to understand better and profit more from the latter instruction in this subject. It is thought that the book will also be useful to the many students “who do not as a rule pursue the subject any further than it is carried in these pages,” but “even more than for the student, this book is intended for the workaday farmer who wants to get an intelligent conception of how his crops and stock make their growth.”

The author is of the opinion that “it should neither be difficult nor tedious for the man with an ordinary education to learn how a plant draws its nutrient from the soil and how the animal depends in its turn upon the plant. . . . Complex and unknown as many of these processes are, the main outlines are sufficiently established to have a bearing upon practice; but the practical application can be more surely and readily made if the farmer, with his inside knowledge of the way things can be done, will learn the theory than by any attempt of the scientific man striving from the outside to get up the working conditions.”

The book is written as far as possible in nontechnical language, and it is assumed that the reader possesses little or no knowledge of chemistry. The main facts and principles are illustrated by numerous simple experiments. Different chapters deal with what the plant is made of, the work of the leaf, the work of the roots, changes of composition within the plant, the origin and nature of soils, cultivation and the movements of soil water, the living organisms of the soil, the chemical composition of the soil, foods, the utilization of food by the animal, food required by the growing and fattening animal, farmyard manure, artificial manures and fertilizers, and milk, butter, and cheese.

Soil improvement, P. van Hoek and A. Rauwerda (Dept. Landb., Nijvo. en Handl., Verslag. en Meded. Dir. Landb. [Netherlands], 1911, No. 1, pp. 45-53).—This article summarizes the results of tests conducted at different places in the Netherlands in the improvement of heath soils by green manures and mineral fertilizers, the fertilizing value of sea mud, stable manure versus
mineral fertilizers for sandy soils, and intensive versus ordinary methods of cultivation.

Among the conclusions it is noted that sea mud gave better results in combination with barnyard manure than with mineral fertilizers. Intensive cultivation, consisting of deeper plowing, better seed-bed preparation, and the use of larger quantities of manure, increased the yield, in some cases as much as 40 per cent.

Experiments on the effect of straw on the action of the nitrogen of green manures, K. Störmer (Fühling's Landw. Ztg., 69 (1911), No. 6, pp. 185-198; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 1911, No. 4, pp. 822, 823).—In the series of pot and field experiments here reported on heavy and light soils the addition of straw to green manure reduced the efficiency of the nitrogen of the latter during the first year, but the results were better the second year. The use of straw alone reduced the yield, and the finer the straw the greater the reduction. Treatment during the second year with carbon bisulphid of soil to which straw had been applied nearly doubled the yield.

Cooperative fertilizer experiments with corn, cotton, rice, cauliflower, peanuts, onions, tomatoes, and potatoes, 1908-1910, G. S. Fraps (Texas Sta. Bul. 138, pp. 5-71).—“This bulletin contains the results of 37 cooperative fertilizer experiments on corn, 21 on cotton, 7 on rice, 1 on cauliflower, 2 on peanuts, 1 on onions, 2 on tomatoes, and 13 on potatoes, carried out... to ascertain the fertilizers adapted to various crops on Texas soils, under Texas conditions, and also to ascertain the relation between chemical composition, pot experiments, and needs of soil as shown by fertilizer experiments.

Dry weather interfered to some extent with the experiments on corn. Acid phosphate at the rate of 200 lbs. per acre increased the yield in 31 of the 37 experiments. The increase averaged from 300 to 440 lbs. per acre of ear corn in the three years. Seventeen of the 37 experiments gave increases with cottonseed meal, which supplies nitrogen mostly. The average increase was greater with 120 lbs. per acre than with 60 lbs. per acre. Corn fertilized with cottonseed meal appears to suffer more quickly from drought than that fertilized with acid phosphate. Potash increased the yield in 12 of the 37 experiments. Where it was needed, it had a considerable effect on the yield. The soils which gave increased yields with cottonseed meal contain on an average less nitrogen than those which did not give increases. When less than 10 parts per million active phosphoric acid was present 2 soils gave increases with acid phosphate and 1 did not, but it is believed the sample did not represent this soil. The average yield without fertilizer on these 2 plats is 4.5 bu. per acre. The average corn possibility in pot experiments, based on phosphoric acid removed, is 4.5 bu. per acre. Six of 9 soils containing 10 to 20 parts per million of active phosphoric acid gave increases with phosphate, and the average yield without fertilizer is about 17 bu. per acre. The average corn possibility based on pot experiments is 12.5 bu. per acre, maximum 31 bu. Four soils containing 20 to 30 parts per million of active phosphoric acid all responded to phosphate, and the average yield without fertilizer was about 24 bu. per acre. The average corn possibility from pot experiments was 20.8 bu. per acre, maximum 36 bu. There was a relation between the average production of corn by the soils and the quantity of active phosphoric acid in them.

“In 17 of 21 cooperative experiments on cotton acid phosphate increased the yield. In 15 of the 21 experiments cottonseed meal increased the yield. Cotton fertilized with cottonseed meal does not suffer so much from drought as does corn fertilized with it. In 10 of the 21 experiments potash increased the yield. It would appear from these experiments that potash is more likely to be of
benefit to cotton on Texas soils than to corn. The effect of Thomas phosphate on corn was less than that of acid phosphate in the 4 tests and greater on cotton in the 2 tests.

"In the experiment on cauliflower the best results were secured with an application of 300 lbs. acid phosphate per acre, 50 lbs. sulphate of potash, 250 lbs. cottonseed meal, with a top dressing of nitrate of soda, equivalent to 600 lbs. per acre of a fertilizer containing 8 per cent phosphoric acid, 5 per cent potash, and 3 per cent nitrogen, followed by the top-dressing with nitrate of soda.

"Potash was effective in 2 experiments on tomatoes. Nitrogen also was effective in one experiment.

"Lime was most effective in the production of peanuts at Rock Island, acid phosphate and potash being also effective. Acid phosphate and Thomas phosphate were most effective in the production of hay at College Station.

"One cooperative onion experiment and three other experiments on onions are reported. Potash gave no results in any of them. Phosphoric acid was most effective at Clyde; cottonseed meal was also effective. Lime was apparently most effective in one experiment at Laredo, but this soil is very rich in lime. Nitrate of soda or cottonseed meal was most effective in another experiment at Laredo. Barnyard manure was the only addition which had much effect at Beeville."

In 13 experiments with Irish potatoes acid phosphate produced results in 10 cases, cottonseed meal in all, and potash in 5. A mixture of equal parts acid phosphate and cottonseed meal, or of 800 lbs. acid phosphate to 1,200 lbs. cottonseed meal, makes a good potato fertilizer for many Texas soils. On some soils the use of potash also would be of advantage.

"In the 71 tests with corn, cotton, and potatoes 59 tests responded to acid phosphate, 45 to cottonseed meal, and 27 to potash. This confirms our conclusions from soil analyses in previous bulletins that Texas soils are likely to be deficient in phosphoric acid first of all, next in nitrogen, and last and least often in potash."

Fertilizer experiments, P. Van Hoek and A. Rauwerda (Dept. Landb., Nij. en Handel, Verslag. en Meded. Dir. Landb. [Netherlands], 1911, No. 1, pp. 1-47).—This article summarizes the results of a large number of fertilizer experiments conducted in different parts of the Netherlands to test the value of mineral fertilizers and stable manure, different nitrogenous fertilizers and the effect of seasonal influence on their action, sodium nitrate versus ammonium sulphate, potash fertilizers on clay and peat soils, phosphatic fertilizers, lime as fertilizer and as a remedy for club root of cabbage, compound fertilizers, and fertilizers for valley soils (dalgronden).

Among the more important conclusions it is stated that mineral fertilizers in general gave better results than stable manure.

With potatoes, ammonium sulphate gave the best yields on peat soils, calcium nitrate on sandy soils, and sodium nitrate on clay soils. Taken as an average for all three soils, however, the order of efficiency was ammonium sulphate, sodium nitrate, calcium nitrate, and calcium cyanamid. On sugar beets the relative efficiency was sodium nitrate 100, ammonium sulphate 99.5, calcium nitrate 99.3, and calcium cyanamid 98.1; and with grain crops sodium nitrate 100, calcium nitrate 98.1, ammonium sulphate 97.5, and calcium cyanamid 95.5.

Kalnit gave better results than a so-called patent potash fertilizer. The after-effects of kalnit were very pronounced. Slag was the most efficient phosphatic fertilizer on potatoes, followed in order by superphosphate, bone meal, and Algerian phosphate. Lime, when applied for several consecutive years, was very efficient in the control of club root of cabbage.
Fertilizer experiments, W. Van Deventer and P. W. Houtman (Meded. Proefsstat. Java-Suikerindus., 1911, No. 9, pp. 133-242).—This article reports the results of a large number of fertilizer experiments on sugar cane conducted during 1910 at the Java sugar experiment stations to test the action of ammonium sulphate at different stages of growth of crop, and as compared with stable manure and in combination with a nitrogenous fertilizer (boengkll), superphosphate, potash applied alone and with nitrogenous fertilizers, and organic matter, sand and stable manure on heavy soils, molasses, lime waste, green manures, and ashes.

Among the more important results obtained it is stated that heavy applications of ammonium sulphate gave better returns than lighter applications. Potash fertilizers when applied either alone or with organic matter gave little or no returns. Sand did not improve the physical condition of heavy soils; stable manure, however, gave good returns thereon.

Molasses fertilizers were very efficient on light soils.

Lime waste, which contained from 60 to 70 per cent lime carbonate, gave very good returns on both light and heavy soils. Green manures gave excellent results, more particularly on soils where the heavy applications of ammonium sulphate had little or no effect on the growth of cane. Ashes appeared to give excellent action on soils poor in phosphoric acid, although the results obtained were not conclusive.

New fertilizers, M. Hoffmann (Mitth. Dent. Landw. Gesell., 26 (1911), No. 28, pp. 386-389).—This article briefly describes and discusses the fertilizing value of aluminum nitrogen, calcium nitrate, calcium cyanamid, Palmaer phosphate, Bernard phosphate, phonolite, zeolite fertilizer, and various other substances which have recently been proposed as fertilizers.

On various nitrogenous fertilizers, G. Ampola (Ann. R. Staz. Chim. Agr. Sper. Roma, 2, ser., 4 (1910), pp. 73-115).—This article gives the results of chemical studies of the behavior of sodium nitrate, ammonium sulphate, calcium cyanamid, and calcium nitrate when mixed with Thomas slag and superphosphate. Results are also given of field tests as to the fertilizing effect of these nitrogenous fertilizers.

The utilization of nitrogen, F. Haber (Verhandl. Naturw. Ver. Karlsruhe, 23 (1909-10), pp. 17-30, fig. 1).—This article deals particularly with the author's apparatus and method for the synthesis of ammonia, but also with the efficiency of different methods of fixing nitrogen as cyanamid and nitric acid.

Nitrofication by ultraviolet rays, D. Berthelot and H. Gaudechon (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 9, pp. 522-524; abs. in Jour. Soc. Chem. Indus., 30 (1911), No. 6, p. 377; Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 1911, No. 3, pp. 528, 529).—“Solutions were exposed, at a temperature of 35 to 50°C, for from 3 to 9 hours at a distance of 3 to 6 cm. from a lamp of 110 volts. Under these conditions the ultraviolet rays oxidized solutions of ammonia in presence of pure oxygen or of air to nitrates. Nitrates were in no case formed. Ammonium salts were also oxidized to nitrates, the reaction being slower in the cases of the sulphate and chlorid than in that of the carbonate. Urea was also converted first into ammonia and then into nitrite. Other organic nitrogen compounds, e. g., ethyl and methylamin, guanidin, hydroxylamin, acetamid, acetonitrile, etc., behaved similarly. Stress is laid on the close analogy between the effects of the rays and of enzimes. The
rays are further able to convert nitrates into nitrites, and they decompose concentrated solutions of ammonium nitrite with liberation of nitrogen."

Commercial production of ammonia, C. G. Tufts (Jour. Indus. and Engin. Chem., 3 (1911), No. 5, pp. 295-299).—The article describes briefly 5 methods which are commercially important in recovering ammonia from coal formations, namely, by means of the gas retort, the by-product coke oven, the Mond gas producer, distillation of shales, and blast furnaces. It is stated that by these methods the world now secures about 1,000,000 tons annually of ammonia measured as sulphate, Great Britain, Germany, and the United States producing about 80 per cent of this amount. The United States product is derived mainly from the by-product coke oven.

The article also briefly refers to the synthesis of ammonia from the nitrogen of the air.

In conclusion the author states that "the old gas retort is gradually losing ground while the output of the coke oven is increasing by leaps and bounds. Meanwhile, in the manufacture of synthetic ammonia and nitric acid, we seem standing on the threshold of a period of such chemical and electrochemical activity as the world has rarely seen."

[Production of ammonium sulphate in England] (Chem. Trade Jour., 49 (1911), No. 1259, pp. 21, 22).—The total production of ammonium sulphate in the United Kingdom during 1910 is stated to have been 367,587 tons. Of this amount 167,820 tons was obtained from gas works, 20,139 tons from iron works, 59,113 tons from shale works, 92,665 tons from coke-oven works, and 27,850 tons from producer-gas and carbonizing works.

Preparation of calcium cyanamid and its uses as a manurial agent (Bul. Imp. Inst. [80. Kensington], 9 (1911), Nos. 1, pp. 44-51; 2, pp. 123-134; abs. in Amer. Fert., 35 (1911), No. 7, pp. 34-39).—This article gives an account of the manufacture of calcium cyanamid and general information regarding its use as a fertilizer, and summarizes the results of field trials on wheat, barley, oats, corn, rice, potatoes, turnips, sugar beets, sugar cane, grasses, hemp, flax, cotton, tobacco, hops, grapes, olives, and onions.

The general conclusions are "that calcium cyanamid can either be harrowed in or applied as a top-dressing, but in most cases the former method gives the better result. The quantity applied should be between 25 and 45 lbs. of nitrogen per acre or 1 to 2 cwt. of cyanamid containing 20 per cent nitrogen. It appears to be advisable to apply the manure when the soil is wet or when there is a prospect of rain.

"As a general rule it may be stated that from the results of experiments the manurial value of calcium cyanamid is about equal to that of sulphate of ammonia when the culture is carried out on a fairly good soil, but is inferior on poor moorland or sandy soil. The beneficial effects of its application are more noticeable when applied to crops which especially need nitrogen for their successful cultivation; but on soils requiring lime as well as nitrogen, calcium cyanamid is likely to give a better return than sulphate of ammonia or nitrate of soda, especially during the second season when the effect of this lime is more noticeable than during the season of application."

Reference is made to the fact that in order to avoid trouble from dustiness a small amount of shale oil is added to the cyanamid.

Potash from feldspar, B. Herstein (Jour. Indus. and Engin. Chem., 3 (1911), No. 6, pp. 426-428).—A process of heating finely ground feldspar in a solution of calcium chloride with subsequent addition of limestone with a view of producing cement and potash salts is described. The process differs from that of Lawrence Smith in the direct use of calcium chloride, thus utilizing a valueless waste product and correspondingly cheapening the process. It is esti-
mated that 190 lbs. of potassium chloride per ton of feldspar could be obtained by this process.

"The residue left after the potash has been removed, by aqueous extraction or otherwise, contains all the essential elements of a cement into which it could be transformed by ignition, supplementing the deficiency of calcium oxide with limestone, if required. No previous grinding would be necessary in this instance, since with the temperature kept reasonably low the mass does not clinker and disintegrate easily in water. Moreover, both the silica and the alumina of the original feldspar have been rendered extremely reactive and should therefore readily form cement on the subsequent operation."

Potash in China (Chem. Trade Jour., 39 (1911), No. 1259, p. 20).—Brief extracts from reports of British consuls in China are given, showing that there is no evidence of the occurrence of natural deposits of potash in that country.

The use of fine ground raw phosphate as a substitute for Thomas slag, T. Remy (Landw. Jahrh., 40 (1911), No. 3-4, pp. 559-611).—Comparative tests of Thomas slag and Algerian, Lahn, and Florida phosphates in field and pot experiments with grasses, grains, peas, lupines, and mustard are reported.

Except in a few cases with winter grain and lupines the raw phosphate was inferior as a fertilizer to Thomas slag. Thomas slag was from 63.8 to 76.6 per cent as effective as superphosphate, and Algerian phosphate from 5.5 to 12.8 per cent as effective. The results with Florida and Lahn phosphates were not materially different from those with the Algerian phosphate. The use of the insoluble phosphates in connection with decaying organic matter or sodium bisulphate greatly increased their efficiency.

Analysis of phosphates as a guide to their conversion into superphosphates, P. Hardy and J. Vandormael (Bul. Soc. Chim. Betyl., 35 (1911), No. 1, pp. 43-57; abs. in Bul. Imp. Inst. [So. Kensington], 9 (1911), No. 1, pp. 52, 53; Chem. Trade Jour., 48 (1911), No. 1355, p. 613).—The authors show as a result of an elaborate study of 3 natural phosphates and of superphosphates made from them "that for industrial purposes the quantity of sulphuric acid necessary to convert a given quantity of natural phosphate into superphosphate may be calculated if the following constituents of the natural phosphate are known, viz., total lime, phosphoric acid, sulphuric acid, ferric oxide, and alumina, and in making analyses of phosphates from new sources it is sufficient for analysts to determine these constituents."

The pyrophosphates, new phosphatic fertilizers in the cultivation of sugar beets, E. Voglino (Coltivatorc, 56 (1910), No. 30, pp. 370-372; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intell. and Plant Diseases, 1910, No. 2, p. 233).—Experiments with 2 commercial products, one simple pyrophosphate, the other acid pyrophosphate, containing 17 and 19 per cent, respectively, of phosphoric acid soluble in dilute citric acid, are reported, the results showing that the first was inferior, the second superior, to superphosphate as regards effect upon the yield of beets. There was, however, no difference in the sugar content in the two cases.

Calcium requirements of plants and the different relations of the calcium and magnesiam in nutritive solutions, N. I. Konovalov (Landw. Vers. Stat., 74 (1911), No. 3-5, pp. 343-369; abs. in Jour. Chem. Soc. [London], 100 (1911), No. 581, II, p. 222).—Previously noted from another source (E. S. R., 25, p. 127).

[The lime-magnesia ratio and chlorosis of citrus fruits], C. B. Lipman and R. R. Snowden (Pacific Rural Press, 81 (1911), Nos. 21, pp. 412, 413; 24, pp. 472, 473).—These articles attack and defend certain conclusions drawn by R. R. Snowden in an article previously noted (E. S. R., 24, p. 525) regarding the relation of the lime-magnesia ratio and chlorosis of citrus fruits.
The value of molasses as a fertilizer, W. E. Cross (Int. Sugar Jour., 13 (1911), No. 148, pp. 191-196).—Analyses showing the fertilizing value of molasses are quoted from bulletins of the Hawaiian Sugar Planters' and Louisiana stations (E. S. R., 18, p. 373; 19, p. 32), and reference is made to experiments which the author is undertaking to determine the fertilizing effect of molasses when applied to soil, especially its relation to the nitrogen content of soils.

Guano deposits of Assumption Island, Seychelles, R. Dupont (Bul. Imp. Inst. [So. Kensington], 9 (1911), No. 1, pp. 39-51; abs. in Jour. Soc. Chem. Indus., 30 (1911), No. 12, p. 760).—The extent, nature, and utilization of deposits of phosphatic guano on this island are discussed. It is estimated that 46,000 tons of a high-grade guano and 50,000 tons of low-grade guano are available.

AGRICULTURAL BOTANY.

Seasonal variation in the food reserves of trees, J. F. Preston and F. J. Phillips (Forestry Quart., 9 (1911), No. 2, pp. 232-243).—The authors present a paper in which their observations regarding the food reserves of trees are described and results of previous investigators are compared.

The work reported in the present paper and that of European investigators indicates that in the stems of all trees in temperate climates there is a reduction in the amount of starch present in autumn, the reduction in some trees being so great as to cause its complete disappearance. In a few trees a considerable increase of fat in the phloem and xylem in the late autumn or early winter is reported, but there is insufficient evidence for the belief that starch is transformed into fat. Both hard and soft wood trees were found to contain considerable fat in winter, and the authors do not agree with European writers who propose classifying hard woods as starch trees and soft woods and gymnosperms generally as fat trees. There is apparently no great increase in the content of sugar in the stems and roots, except in the spring as the buds unfold. In the root, transformations do not keep pace with those of the stem, and starch remains throughout the year, the greatest reduction occurring in the spring.

The transformations of carbohydrates are generally dependent on the season, although immediate conditions of temperature have some effect. As has been pointed out by others, the authors found that the maximum for total carbohydrate reserves of deciduous trees is at the fall of the leaf in autumn, whereas for the persistent-leaved trees the maximum is at the opening of buds in the spring.

On the chemotropism of plant roots, T. Porodko (Jahrh. Wiss. Bot. [Pringsheim], 49 (1911), No. 3, pp. 307-388).—After a brief review of the work of other investigators on this subject, the author describes the methods used and gives the results obtained in a series of experiments on the chemotropism of the roots of Lupinus albus and Helianthus annuus when grown in the presence of various salts in agar-agar as a diffusion medium.

The lupine roots reacted by curving, which occurred only with definite concentrations of a given salt. The upper and lower parts of the roots themselves remained straight. Only the intermediate zone showed the curved reaction, which varied in intensity, in form, and in direction according to the salt and concentration under consideration. The angle of divergence of the curvature varied between 0 and 90°, due to the action of two forces, namely, the stimuli of the salts used and gravity. The first acted on the roots in a horizontal direction, i. e., at right angles to the main axis of the root, while gravity, on the contrary, acted in a vertical direction, i. e., in the direction of the main axis of the roots. According to the relative intensity of both forces, the roots
took certain position between 0 and 90°. The geotropic disposition of the roots remained constant throughout in the agar medium, so that the intensity of the curving depended only on the intensity of the diffusion forces or stimuli, and this varied with the nature of the salt or diffusion substances used, with the concentration, with the thickness of the agar block, and with the length of time the diffusing currents acted.

The form of the curving was determined by the point on the root at which the curve occurred and the appearance of the curved line. Some curves were localized near the root tips and were sharply angular, while others began in the higher zones of the root and were bow-shaped. Between these two extremes there were different transition forms.

The reaction as to the direction of the curvature, due to the concentration, manifested itself by a check in the growth and a positive curvature of the roots. This effect was observed generally in all substances tested, both electrolytic and nonelectrolytic. When the concentration became greater a difference between the reaction to electrolytic and nonelectrolytic substances manifested itself. In diffusion streams of nonelectrolytic content the roots in general were unaffected. In the case of electrolytic substances there was observed a dominant direction curve which was positive in the case of acids, alcalis, sodium carbonate, and potassium carbonate, and negative in the case of neutral salts. The differences in curvature are referred to the action of individual electrolytes. A strong positive curve was generally observed in alkaline solutions, while acids produced positive but weak curves. Positive curvatures were probably due to the presence of H and OH ions, while the negative curve seemed to depend on the strength of the solution independent of the nature of the cation. Salts with divalent cations, as magnesium and strontium, produced, independently of the nature of the anion, a negative curve. Salts with univalent cations, as lithium, sodium, potassium, and ammonium, showed less negative curvature.

The article closes with tables showing the effects of each substance used on the root curvatures and with a general discussion of the results obtained.

Researches on the formation of nitric acid in living cells, P. Mazë (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 23, pp. 1624–1627).—The author claims that 6 species of bacteria, some aerobic and some anaerobic, form nitric acid when grown in a medium consisting of ammonium chlorid, tripotassium phosphate, magnesium sulphate, iron sulphate, sodium chlorid, calcium carbonate, saccharose, and water.

On the assimilation of atmospheric nitrogen by green plants, EVA MAMELI and G. POLLACCI (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. c Nat., 5. ser., 20 (1911), I, No. 9, pp. 650–657; Bul. Soc. Bot. Ital., 1911; No. 2, pp. 16–21; abs. in Nature. Rundschau, 26 (1911), No. 38, pp. 483, 485).—This is a further study (E. S. R., 24, p. 29) of the fixation of free nitrogen by green plants, in which seedlings of Acer negundo, Solanum nigrum, Cucurbita pepo, Raphanus sativus, and Polygonum fagopyrum were grown in sterilized nitrogen-free media. Tabulated results are given of the amount of nitrogen in each plant compared to that in the seed from which they grew.

The authors claim as a result of these experiments that under special conditions the power of assimilating free nitrogen is possessed by many green plants.

On the need of lime salts in the metabolism of the fungus Coprinus, J. R. WEIR (Flora, n. ser., 3 (1911), No. 1, pp. 87–90).—As a result of experiments the author concludes that lime compounds are as necessary for the life and development of the higher fungi like Coprinus as for the higher algae and other green plants.
The mechanism of carbon assimilation, III, F. L. Usher and J. H. Priestley (Proc. Roy. Soc. [London], Ser. B, 84 (1911), No. B 569, pp. 101–112, figs. 2).—In previous papers (E. S. R., 18, p. 540) the authors presented their conclusions on investigations relating to carbon assimilation, some of which have since been criticized. They have repeated their investigations, modifying them to some extent, and in the present paper they discuss the initial stages of the assimilation process without reference to the synthesis of sugar or starch.

The previous conclusions are modified, the authors having abandoned the idea of the exclusive localization of catalase in the chloroplasts and also the dependence of the post-mortem bleaching of chlorophyll on the presence of carbon dioxide. They believe now that they are justified in considering the primary products of the photolysis of aqueous carbon dioxide to be formaldehyde and hydrogen peroxide, and that the evolution of oxygen is due to the decomposition of the latter substance by catalase. Up to this point the process is entirely nonvital and can be readily produced artificially.

The relation of the odorous constituents of certain plants to plant metabolism, F. Rabak (Jour. Amer. Chem. Soc., 33 (1911), No. 7, pp. 1242–1247).—In an investigation on the odorous constituents of a number of species of plants, the author has studied their relation to plant metabolism, and in general believes that the esters do not manifestly seem to be affected during the fruiting of the plant. There does, however, appear to be a period in the growth and development of plants when, with the assistance of certain favorable conditions, the chemical processes in the plant transform some of the basal constituents into esters and corresponding alcohols. The odorous constituents formed in plants are believed to be simply products of excretion formed during the metabolism of the plant and are of no further use to the plant, since they are not obviously utilized for any special purpose other than possible means of protection against insect enemies.

A research on the origin of alkaloids in plants, G. Ciamician and C. Ravenna (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 20 (1911), I, No. 9, pp. 613–624).—In the experiments reported, Datura and tobacco were inoculated with certain nitrogenous and nonnitrogenous substances, and the resulting effects on the alkaloidal content were noted. The authors state that no positively definite conclusions can be drawn from their experiments, but that they indicate that the vegetable alkaloids are derived from the amido acids.

On the direct guaiacum reaction given by plant extracts, Miss M. Wheeler (Proc. Roy. Soc. [London], Ser. B, 84 (1911), No. B 569, pp. 121–124).—In the literature dealing with oxidizing enzymes attention is drawn to the fact that the juices of some plants change guaiacum tincture directly while others bring about a bluing only on the addition of hydrogen peroxide. Various explanations have been given to this fact, some claiming that the reduction is due to a second enzyme, oxygenase. Doubt, however, has been cast on the existence of such an enzyme, and the author has carried on experiments and found that the power giving rise to direct guaiacum action in any plant is always accompanied by another phenomena, i. e., the formation of brown or reddish-brown pigment when the tissues are injured mechanically or are subjected to chloroform vapor.

The author's observations have led to the conclusion that the direct action given by the extracts of plants examined is due to the presence of pyrocatechinate in the tissue of the plants, which rapidly oxidizes on exposure to the air and then acts as an organic peroxide, enabling the peroxidase, which is almost universally present, to transfer oxygen to the guaiacum. The plants which the author examined and which were not found to contain pyrocatechin did not give the direct action.
Inheritance of fascination in Zea mays, H. Hus and A. W. Murdoch (Plant World, 14 (1911), No. 4, pp. 88-96, fig. 1).—In a general discussion of the question of the inheritance of teratological characters, the author gives the results of experiments on the inheritance of fascination of the ears of Z. mays everta. A comparison of the results obtained from unfasciated and from fasciated ears indicates that fascination is not a matter of mere accident but one of inheritance, and is subject to the same laws as are other characters.

A case of gametic coupling in Pismum, P. de Vilmorin and W. Bateson (Proc. Roy. Soc. [London], Ser. B, 84 (1911), No. B 568, pp. 9-11, fig. 1).—Observations are reported on breeding experiments with peas in which there was found a coupling of the factors of round peas and tendril bearing and wrinkled peas and nontendril bearing. The results of a series of observations on the F₁ generation showed that for the round seed 319 bore tendrils and 4 were without, while the wrinkled seed gave 3 tendrilled and 123 nontendrilled leaves.

On the microflora of soils in the vicinity of Rome, R. Perotti (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 20 (1911), I, No. 9, pp. 690-694).—In a general discussion of the bacteria of these soils the author tabulates the number of bacteria per cubic centimeter of soil at depths of 10, 20, 35, and 50 cm. in tufaceous and other soils during the different months of the year, and compares the microflora of these soils.

FIELD CROPS.

Work of the Gocding substation, F. D. Farrell (Idaho Country Life, 4 (1911), No. 9, pp. 13-15, 19).—During the duty of water investigations reported in these pages it was observed that the average weekly evaporation was 1.79 in., and the maximum and minimum 2.44 and 1.01 in., respectively. The precipitation during the growing season, or from April 1 to September 30, was 1.41 in. The principal data secured are given in the following table:

It is noted that the yield was almost directly proportional to the amount of water applied, but that a point of diminishing return was finally reached, the efficiency of the water being highest on a series of 27 plots not included in the above table when approximately 12 in. of water was applied.

Reports of the yields of various other crops are given. In a test of 32 varieties of spring wheat, all irrigated 4 times, the durum variety Pollister produced the highest yield, 40.15 bu. per acre. Among 4 barleys White Smyrna
yielded 61.8 bu., and among 16 varieties of oats Big Four produced the highest yield, 91.33 bu. per acre. Among 5 clover varieties red clover yielded 8 tons of forage per acre as compared with 4.12 tons from white clover, the lowest yield. *Bromus inermis* proved remarkably resistant to cold and was 5 in. high in 1910 before any other grass in the test commenced growth. Among 9 millet varieties California produced the highest yield of forage, 5.5 tons per acre. Among the 6 sorghum varieties Red Amber produced more than 13 tons of forage per acre. Cassia Flint corn excelled 3 other varieties with a yield of about 100 bu. per acre.

Results of crop experiments, A. J. Nicoll (*Hoard's Dairyman*, 32 (1911), No. 29, pp. 651, 655).—This article reports results obtained by the president of the Delaware County Agricultural Society and manager of the experiment station work at the Delaware County Farm.

In a test of 12 varieties State Flint Yellow corn yielded 46.85 bu. per acre.

In a breeding experiment 120 potatoes of the Sir Walter Raleigh variety were selected for uniformity of size and shape. Each tuber was cut into 4 pieces. When harvested the yield from the parent tubers varied from 2 lbs. of inferior to 8 lbs. of fine, smooth potatoes. One tuber yielded 24 potatoes, 19 of which were marketable, while another tuber, apparently equally good, yielded only 12, 1 of which was marketable.

During this year Federation wheat produced an average yield of 25.79 bu. on the 12 farms included in the test, while College Purple Straw and Yandilla King yielded 21.47 and 21.03 bu. per acre, respectively. On 10 farms higher average yields were secured from fields seeded at the rate of 65 lbs. per acre than at higher or lower rates. Among the oat varieties, Garton Stout White and Algerian produced the highest average yields, 33.29 and 32.24 bu. per acre, respectively.

Government experimental farms, 1910, A. E. V. Richardson (*Jour. Dept. Agr. So. Aust.*, 14 (1911), No. 8, pp. 735-747, figs. 6).—A progress report is given of 3 generations of wheat breeding work based upon crosses of selected Canadian hard reds, Indian, and Hungarian varieties on Federation, Gluyas, Yandilla King, and other local Australian wheats.

At the Loxton Experimental Farm, situated on the banks of the River Murray, Baroota Wonder and Bunyip produced the highest yields of 24 and 22 bu. per acre in a test of 9 varieties of wheat. In a test of applications to Federation wheat of superphosphate in amounts ranging from 30 to 150 lbs. per acre, the 2 highest applications, 75 and 150 lbs., were followed by exactly the same yield, this excelling that of lower rates. In a similar test with Cumberland wheat sown at the rate of 50 lbs. per acre, the highest yield, 30 bu. per acre, followed the application of 150 lbs. of superphosphate per acre, but an increase of from 22 to 27 bu. per acre followed the addition of 56 lbs. of nitrate of soda to 45 lbs. superphosphate and 30 lbs. of sulphate of potash. Both mixtures were followed by a slightly lower yield than was secured with 45 lbs. of superphosphate alone. In a cultivation test wheat receiving no cultivation other than a slight stirring incident to drilling produced almost as much grain as that planted on ground that was cultivated during the preceding fall. Yields about 4 bu. higher were secured on ground plowed 3 to 4 in. deep.

In a test of 4 varieties of oats, Scotch Grey produced the highest yield, 18 bu. and 30 lbs. In a test of 4 wheat varieties Cumberland and King Red produced
about 15 bu. each. In a test of 14 other wheat varieties Gluyas produced the highest yield, 28 bu. per acre.

Report of Hedemarcken county experiment station, 1910, W. Christie (Ber. Hedemarckens Amts Forsöksstat. Virks., 6 (1910), pp. 58, pls. 3, figs. 5).—The author reports the results of tests conducted during 1907–1910 of different dates for planting potatoes, of work conducted in 1910 on the starch content of potatoes, of storing potatoes, and of work with oats in 1909 and 1910.

In the potato storage tests 2 piles of the General Cronje variety were made 1½ meters wide by 3 meters long and as high as they would lie, none being placed beneath the soil surface. Two other piles were placed in trenches 3 meter deep, ½ meter wide, and 3 meters long, and piled as high above the ground as they would lie. All were covered with 2 layers of straw alternating with 2 layers of dirt. In the 2 large piles were stored 1,352 and 1,203 kg. of potatoes, respectively, and in the smaller ones 632 and 611 kg. The larger piles were ventilated at the surface of the ground and at the top of the pile, the smaller ones being ventilated only at the top. The storage period extended from November 1, 1908, to April 20, 1909. The temperature readings presented for 10-day intervals showed a minimum for the period of −23.9° C.

On opening the piles only a few potatoes in the top layer were frozen, but bacterial rot had spoiled considerable quantities, apparently because of the moist condition of the potatoes when stored. In the large piles 43 per cent of the tubers were sound as compared with 54 per cent in the small piles. In view of the difficulty of getting the potatoes into storage sufficiently dry in the fall, the author does not recommend the method tested but prefers the use of potato cellars, the average expense of which he estimates at 1 krone per 100 kg. of potatoes (12.2 cts. per 100 lbs).

A comparison of strains of pure-bred Norwegian gray oats, white oats, and Probsteler oats showed that the 3-kernel characteristic increases with the number of whorls, but comparisons of different strains of the same variety failed to show that these characteristics stand in either a direct or an indirect relation to one another. The 3-kernel characteristic likewise increased with the kernel weight per plant when comparison was made within the same pure-bred strains, but no regularity was traceable between different strains of the same variety. The author, therefore, considers the 3-kernel characteristic one that gives information concerning the luxuriance of the individual plant only, and not of the productiveness of the strain, so that he regards the characteristic as of no value in making comparisons between strains within the same variety. The kernel weight per plant gives much more certain information as to the yield of the strains and may furthermore be determined considerably more easily and more rapidly.

Alfalfa in northwest Texas, A. B. Conner (Texas Sta. Bul. 137, pp. 17, pl. 1, fig. 1).—These directions for producing alfalfa in northwest Texas and utilizing it for hay, seed, and forage are based on farm experience in that region and 5 years' experimental work by this Department and the Texas Station in cooperation.

The improvement of the Proskowetz-Original-Pedigree barley, E. von Tschermak (Wiener Landw. Ztg., 60 (1910), No. 11, pp. 98, 99; abs. in Jour. Landw., 58 (1910), No. 2, p. 137).—Since 1904 the author has grown Hanna barley, a local variety, the value of which was first recognized by von Proskowetz. An increase in tillering power, fineness of hull, and early maturity by selection, spontaneous crossing, and by open blossom was observed.

Red clover, J. M. Westgate and F. H. Hillman (U. S. Dept. Agr., Farmers' Bul. 455, pp. 48, figs. 25).—It is thought that the data here summarized "will
enable farmers in the clover-producing States to continue the growth of this crop with more certainty of success than is at present the case in many sections."

A description of the plant and statements of its history, distribution, and soil and climatic requirements are followed by discussions of the following topics: Obtaining a stand, handling the crop, red clover in mixtures and in rotations, red clover as a feed and a soil improver, seed production, varieties, insect enemies (by P. M. Webster), fungus diseases, and clover sickness.

Inheritance of row-numbers in maize ears. J. Burt-Davy (Nature [London], 86 (1911), No. 2167, pp. 337, 348).—The Arcadia White Sugar maize is the result of a cross between the 8-rowed Black Mexican and a white flour-corn which normally bears a large number of rows. Thirty-three plants of Arcadia bearing 2 well-developed ears each were studied with special reference to the number or rows. In 12 plants the lower ear had as many rows as the upper ear, in 13 cases it had more, and in 8 cases fewer. Among the 66 ears 11 were 8-rowed, 23 10-rowed, 30 12-rowed, and 2 14-rowed.

Maize from Nyasaland and the Gambia (Bul. Imp. Inst. [So. Kensington], 8 (1910), No. 4, pp. 369, 370).—These pages report the results of the examination and valuation of white and yellow maize samples submitted by the director of agriculture at Zomba and described as grown in the Port Herald district.

The shrinkage of corn in storage, J. W. T. Duvel and L. Duval (U. S. Dept. Agr., Bur. Plant Indus. Circ. 81, pp. 11, figs. 3).—This is a statement of observations made on 500 bu. (28,000 lbs.) of shelled corn stored in the wooden hopper of a scale in a Baltimore elevator. The corn remained in the hopper from January 5, 1910, until May 14, 1910, without handling "It was then run out of the hopper and elevated 3 times to the same scale," and laid 18 days longer, making 147 days in all in storage.

On January 5 the average moisture content of the corn was 18.8 per cent. Its temperature and that of the air were 20° F., its germination test 89.6 per cent, and its weight per bushel 54.7 lbs., while 97.1 per cent of the corn was sound. On June 1 the moisture content was 14.7 per cent, the weight per bushel 50 lbs., the germination test 1 per cent, and only 1.1 per cent of the corn was sound. The total shrinkage during the storage period of 147 days, exclusive of the loss of 448 lbs. during the 3 elevations, was 1,522 lbs., or approximately 5.6 per cent.

It was observed "that whenever there was an increase in weight or a retardation in the shrinkage the relative humidity of the atmosphere was very high between weighings, and in most cases a heavy rainfall occurred just before such weighings were made." The shrinkage in weight from January 5 to April 21, while the corn remained in good condition, was approximately four-tenths of 1 per cent, but from April 21 to May 14, during which time the corn became sour and hot, with a maximum temperature of 138° F. on May 2, the shrinkage was approximately 2.6 per cent. During the 3 elevations on May 14, on a basis of the actual weight of corn in the hopper just before handling, the shrinkage was 1.65 per cent. After the corn had been cooled to 55° F. by handling, the shrinkage in storage from May 14 to June 1 was 2.6 per cent. So long as the corn remained in good condition its rate of shrinkage was largely influenced by the relative humidity, air temperature, and other weather conditions.

The problem of the improvement of cotton in the United Provinces of Agra and Oudh, H. M. Leake and A. E. Parr (Agr. Jour. India, 6 (1911), No. 1, pp. 1-13, pls. 5).—A review of the problems involved in cotton improvement in Agra and Oudh is followed by a discussion of progress already made.
The authors have shown that the cotton grown throughout the provinces consists of a mixture of types. The flowers are of 3 colors due to 2 color characters, yellow and red. "When both colors are present the flower has the full red color; when red is present and yellow is absent the flower is pink, while if yellow is present and the red absent the flower is yellow."

The plant sought by the authors in their work must be ripening fruit by the beginning of October if sown at the beginning of the rains, thus having a vegetative period of from 70 to 80 days. It must flower early and be a vigorous heavy yielder, with a fine, long, silky lint. A red flower is an important although secondary requirement, as it is an easily detected feature and aids in disclosing the mixture of impure strains. Crosses between Nurma and a short, staple, silky Pani, and between Nurma and a white-flowered Desi have been relied on for practical results in earlier experiments which are discussed.

Suggestions for cotton growers, R. H. B. Dickson (Rhodesia Agr. Jour., 8 (1911), No. 4, pp. 563-583, pl. 1).—A brief review of the world's cotton supply and demand is followed by itemized statements of the cost of producing and marketing the crop in the Transvaal, and an itemized statement of the average cost per acre on 3,325 plantations in the southern part of the United States. The total cost per acre given is £3 4s. 6d.

Cotton cultivation: Prospects in Transvaal, T. A. J. Place (Agr. Jour. Union So. Africa, 1 (1911), No. 1, pp. 58-64, pls. 2).—The author presents estimates of the cost of production and the returns per acre of cotton, indicating a profit of £1 8s. per acre. He states that at the Barberton experiment station Doughty Big Boll, Black Rattler, and Cook Long Staple yielded 1,292, 1,272, and 1,224 lbs. of seed cotton per acre, respectively, while at the Tzaneen station in the Zoutpansberg district equally satisfactory results have been obtained.

Cotton growing in German East Africa, L. Hamilton (United Empire [Gl. Brit.], n. ser., 2 (1911), No. 6, pp. 410-415, map 1).—This is a discussion of the possibilities of avoiding the "American cotton monopoly" by the development of cotton growing in German colonies.

Some problems connected with the introduction and cultivation of exotic cottons in Nyasaland, J. S. J. McCall (Nyasaland Dept. Agr. Bul. 1, 1911, pp. 8).—A statement of the climate, insect pests, and other local conditions with special reference to cotton growing in Nyasaland accompany suggestions on the choice of seed.

Field pea production in Washington, M. W. Evans (Washington Sta. Bul. 99, pp. 4-22, figs. 4).—In this report of investigations in cooperation with the Bureau of Plant Industry of this Department, statements of some cultural and other characteristics of 6 varieties are followed by directions for growing, harvesting, thrashing, and utilizing field peas in Washington.

In a rate of seeding test conducted during the very dry summer of 1910 the maximum yield of Kaiser followed seeding at the rate of 127 lbs. per acre, but in case of Bangalia 73 lbs. appeared to be the best rate.

Rice, J. Kenny (in The Coconut and Rice. Madras, 1910, pp. 25-58).—In a test of 7 different fertilizer mixtures applied at various rates applications of (1) 6 maunds (493 lbs.) of bone meal, (2) 3 maunds of bone meal, and (3) 100 maunds of cow dung were followed by yields of 3,962, 3,663, and 3,556 lbs. of grain per acre. These were 12-year averages for the period ended in 1903. Tables state the results of other fertilizer tests with rice.

Sisal hemp in Fiji, C. H. Knowles (Dept. Agr. Fiji Bul. 1, 1911, pp. 16, pls. 2).—Directions for growing and harvesting the crop and for extracting the fiber are followed by statements of results obtained at the experiment station.

The best two sweet sorghums for forage, A. B. Conner (U. S. Dept. Agr., Farmers' Bul. 458, pp. 23, figs. 7).—The author regards Amber as the best
sorghum in the section north of the central line of Kansas and Missouri, and Sumac south of it. In a test of 8 sorghum varieties conducted in northwestern Texas the growing periods ranged from 92 days in case of Red Amber to a maximum of 120 in case of Gooseneck, while the yield ranged from 4 tons in case of Minnesota Amber to 7½ tons each in case of Sumac, Gooseneck, and Honey. The number of leaves, degree of sweetness, juiciness, and tenderness, and the principal objections are stated in connection with each variety.

Descriptions of the varieties tested are followed by discussions of the factors limiting sorghum growth; means of securing the best forage yields; sorghum-cowpea mixtures; growing pure and improved seed; and harvesting, curing, storing, feeding, and marketing the crop.

The Eckendorf breeding standard, SCHMELZER (Illus. Landw. Ztg., 30 (1910), No. 1, p. 2, fig. 1; abs. in Jour. Landw., 58 (1910), No. 2, p. 134).—The author calls attention to the fact that von Vogelsang has established a model for the Eckendorf type which can readily be adapted to other beet types. It provides for the designation of the size and form of the beet by means of 7 figures.

Yields of sugar canes: Crops of 1910, J. R. HARRISON and F. A. STOCKDALE (Jour. Ed. Agr. Brit. Guiana, 4 (1911), No. 3, pp. 210-212).—These pages report data from plantation reports, showing the acreage devoted to each of a number of cane varieties as well as the yield secured.

Winter wheat in western South Dakota, C. SALMON (U. S. Dept. Agr., Bur. Plant Indus. Circ. 79, pp. 10).—This paper deals with the advantages of, and difficulties likely to be encountered in, growing winter wheat in the semiarid section of western South Dakota.

In a 3-years’ test at the Bellefourche experiment farm the average winter killing of the best varieties was less than 15 per cent. Three-years’ variety tests showed no varieties superior to the Russian winter wheats Kharkof and Turkey. The author considers summer fallowing the best method of preparing the seed bed, although this is likely to increase the danger from soil blowing. Data are given concerning a 3-years’ experiment to ascertain the best time of seeding winter wheats but the results obtained were not uniform.

The author recommends early sowing at the rate of 3 pk. per acre if the seed bed is well prepared and there is sufficient moisture to germinate the grain.

A new English wheat variety, H. FABER (Tidsskr. Landøkonomi, 1911, No. 4, pp. 237-244).—The history and special characteristics of the wheat variety Burgoyne Fife are discussed.

Work done under the seed control act, H. L. BOLLEY (North Dakota Sta. Rpt. 1909, pp. 67-93, figs. 2).—During the six months ended December 31, 1909, the seed laboratory received 10 miscellaneous samples for identification, 302 samples of field seeds for purity or germination tests, and 131 samples of garden seeds and 277 samples of flower seeds for germination tests, the results of which are summarized. An enumeration is also given of the principal weed seeds found in the field seeds. The methods of examination are briefly described.

Experiments conducted during the year with the so-called “hard” seeds of legumes indicate that such seeds will not when planted germinate sufficiently quickly to be of any advantage to the farmer. Tests with “hard” clover seed treated with hot water at a temperature of 80° C. for 1, 2, and 4 minutes, at 90° for 1 minute, and with 0.1 of one per cent caustic potash solution for 1
hour, also at 80° C for 1 and 2 minutes, and 70° C for 1 minute, showed that neither the untreated seed nor any one of the treated samples succeeded in producing as many plants in the field as the sample produced sprouts in germination tests. The highest percentage of field growth was 61.7 per cent, while the average of 40 tests in the laboratory showed 77 per cent.

Evidence is submitted controverting the contention of seedsmen that alfalfa dodder does not mature seed in the Northwest.

Work with weeds, H. L. Bolley (North Dakota Sta. Rpt. 1909, pp. 56, 57).—Attempts to procure a substance destructive to quack grass and sow thistle without being injurious to the soil have as yet been essentially negative. As a chemical of cheap grade which would be destructive to dandelions and non-injurious to grasses, stone walks, clothing, etc., calcium chloride has been used with considerable success, though not as yet recommended as a substitute for iron sulphate.

The extensive field trials with iron sulphate against dandelions previously noted (E. S. R., 19, p. 56) were continued. It is concluded that this treatment is quite practical on large lawns, and that the cost, using field sprayers, is less than that for mowing such lawns.

The beneficial effect of the iron sulphate in preventing diseases of blue grass was again noted.

Weeds of the farm and garden, L. H. Pammel (New York and London, 1911, pp. XI+281, pl. 1; figs. 174).—The author presents a partial bibliography, consisting of easily accessible references, and devotes particular attention to descriptions of some common weeds. He deals with many more forms from eastern North America than from the Pacific coast or the Southern States, and presents numerous new drawings. Special chapters are devoted to the nature of the crop injury due to weeds, a classification of weeds based on duration, the dispersal of weed seeds, seed testing to detect impurities, weed laws and seed-control laws, weeds of special crops, poisonous and noxious weeds, migration, extermination, and morphology of weeds, and treatment for special weeds.

HORTICULTURE.

A new method of shortening the rest period of woody plants, F. Jesenko (Ber. Deutsch. Bot. Gesells., 29 (1911), No. 5, pp. 273–284, pl. 1; abs. in Gard. Chron., 3. ser., 50 (1911), No. 1286, p. 131).—The method of forcing plants recently experimented with by the author consists in injecting into the stems dilute solutions of alcohol or of ether, and likewise of water. The injection fluid is contained in a vessel and subjected to a pressure of about one atmosphere, side tubes connecting the vessel with the branches to be forced. Solutions of different strengths were used.

Tests conducted in December with the common lilac, Forsythia, and the flowering plum gave negative results. In January, however, the branches of a number of trees were successfully forced both with alcohol and with ether as well as with the water injection. With the black locust, for example, it was shown that a 5 per cent solution of alcohol, or 0.1 per cent ether solution, injected into cut branches caused the buds to expand about 3 weeks earlier than untreated branches. A number of consecutive tests with black-locust branches indicate that the treatment is only effective in stimulating the buds during the rest period. The failure to stimulate the buds of the above-named shrubs is attributed to the fact that these shrubs had practically passed through their rest period and were only awaiting favorable weather conditions, such as may be obtained in the greenhouse, to start growing.
A number of hornbeam branches were taken from the woods and treated in February. The treated buds from branches growing on the periphery of the tree developed much quicker than the control buds, whereas the treated buds on branches taken from the undergrowth were much slower in development than the control buds.

The general conclusion is reached that certain concentrations of alcohol and of ether as well as pure water exert a beneficial influence in forcing plants. For alcohol the concentration may range from 1 to 10 per cent and for ether from 1 to 0.01 per cent. The use of these injections subsequent to the rest period, however, may result in injury, if not in death, to the branches.

A brief bibliography is appended.

The wounding method: A new process of forcing plants, F. Weber (Österr. Gart. Ztg., 6 (1911), No. 7, pp. 241–245, figs. 2).—The method described consists in piercing the individual buds of the plants to be forced with an ordinary medium-sized needle. The incision is made at the base of the bud and the needle point is allowed to penetrate to the center of the bud.

The development of linden buds which were pierced in this manner during the after-rest period, or about the end of January, was from 2 to 3 weeks earlier than that of the unpierced buds. Lilac and linden buds pierced in this manner were also given an injection of water, the resulting development being quicker and stronger than piercing with the needle alone. The water injection acted less favorably with beech and maple. Thus far the experiments have not been sufficient to determine the practicability of this method with the ordinary forcing plants.

Report of the government horticultural experimental fields in South Holland for 1910, C. H. Claassen et al. (Verslag Rijksstuinbouwproefvelden Zuid-Holland, 1910, pp. VII+80).—Results are given of a large number of cooperative cultural, variety, fertilizer, and spraying experiments with fruits and vegetables, conducted at different localities in South Holland during 1910.

The control of insects and diseases affecting horticultural crops, H. R. Fulton, W. J. Wright, and J. W. Gregg (Pennsylvania Sta. Bul. 110, pp. 3–44).—This bulletin contains concise descriptions of the principal insect enemies and fungus diseases of fruits and vegetables, and suggests methods for controlling them. Most of the remedies suggested have been verified by trials at the station.

Presence of arsenic in fruit sprayed with arsenate of lead, P. J. O’Gara (Science, n. ser., 33 (1911), No. 858, pp. 900, 901).—The author points out that many brands of arsenate of lead used for spraying fruit do not show sufficient uniformity in arsenic content, nor is the arsenic found in the proper combination with lead. Upon examination of a number of apples held in storage which had developed red and black spots, it was found that such fruits contained arsenic, and that the badly spotted fruits showed about twice as much arsenic as unspotted fruits from the same lot. A 10-gm. sample of badly spotted apple skin showed 0.05 mg. of metallic arsenic. One large Spitzenburg apple showed a total of 0.3 mg. of arsenic calculated as As₂O₅.

It was also noted that certain papers used for wrapping apples and pears very frequently contain small amounts of arsenic, as well as other substances, which may or may not have an injurious effect. In one case under observation a shipment of pears of one variety from the same orchard was wrapped in 2
different brands of paper. An examination of the whole shipment after it had been in storage for some time showed that the condition of the fruit corresponded exactly with the brand of paper used, the ripening process of one lot being much in advance of the other.

The principles of pruning, E. Lucas (Die Lehre vom Baumschnitt für die deutschen Gärten bearbeitet. Stuttgart, 1909, 8. ed., rev. and enl., pp. XVI+334, pls. 8, figs. 256).—A practical guide to the pruning and training of fruit trees, vines, and bushes, with special reference to German conditions. Consideration is also given to the pot culture of fruit trees and protection of fruit against weather conditions, insects, etc., and harvesting and storing fruit.

Fruit tree planting, C. B. Waldron (North Dakota Sta. Rpt. 1909, p. 95).—All of the young fruit trees in the station plantation were killed by hail in 1908 and were replaced with standard varieties of apples and plums considered suitable for the climate. The rapid spread of the Exoascus or so-called "plum pocket" is considered a very serious menace to plum growing and will necessitate the selection of resistant strains.

Progress in the breeding of hardy apples for the Canadian Northwest, W. Saunders (Canada Cent. Expt. Farm Bul. 68, 1911, pp. 14, pls. 3).—The author has been engaged for the past 24 years in an attempt to breed a hardy race of apples for the Canadian Northwest. This bulletin reviews the history of this investigation and gives the results thus far secured.

The first plantings were made in 1887 from seeds of Pyrus baccata, obtained from the Royal Botanic Gardens, St. Petersburg, Russia. In 1894 P. baccata was crossed with pollen from many of the hardiest and best sorts of apples grown in Ontario. Other species were subsequently used in the breeding investigations. The crosses herein described include 17 crosses of P. baccata with some of the best cultivated apples, together with 13 additional and less desirable crosses with P. baccata, 10 crosses with P. prunifolia with some of the best cultivated apples, and a cross of P. prunifolia intermedia with McIntosh Red. Within recent years crosses of P. baccata conocarpa and P. baccata sanguinea with cultivated varieties have also been made. A list is given of second crosses now in the orchards on the Central Experimental Farm, Ottawa, and 2 of the most promising of these. Margery and Martin, are herein described as well as the 3 following crosses which gave promise of unusual hardiness: Rideau, a cross of Wealthy with Duchess; Fairfield, a cross of Hyslop Crab with Duchess; and Salmon, a cross of Duchess and Anis.

Judging from the results thus far secured the author is of the opinion that in a very few years a number of varieties of apples will be available, possessing the requisite hardiness, size, and quality for culture in all those portions of the northern country where ordinary apples can not be grown.

Is it necessary to fertilize an apple orchard? U. P. Hedrick (New York State Sta. Bul. 339, pp. 153–195, pls. 4, figs. 7).—This bulletin contains a detailed account of a 15-year experiment to determine whether it is necessary to fertilize apple orchards.

The experiment was carried on in a station orchard composed of Rome Beauty apples top worked on Ben Davis and set out in 1896. The soil is a clay loam, too heavy for a good orchard soil and not better than the average clay soil in the farm lands of western New York. The orchard has been given the care as to tillage, pruning, spraying, etc., that it would receive in a commercial plantation. Beginning with 1900, 2 plats of 5 trees each have received an average of 415.15 lbs. of stable manure per tree; 2 plats an average of 12.66 lbs. of P₂O₅ per tree; 2 plats an average of 7.26 lbs. muriate of potash and 12.8 lbs. acid phosphate per tree; and 2 plats an average of 7.26 lbs. of muriate of potash.
12.6 lbs. acid phosphate, 3.67 lbs. nitrate of soda, and 12.84 lbs. dried blood per tree. The fertilizers were applied as soon as the ground could be tilled in the spring, and they were only applied underneath the branches of the trees, so that a tremendous excess of each has been used. The results, which are presented in tabular form and fully discussed, were gauged by the yield, size, color, flavor, maturity, and keeping quality of the fruit; the diameter of the tree; the amount, color, and weight of foliage; and the length and weight, as well as the annual growth of the branches.

As compared with the checks the fertilizers had no sensible effects upon the yield of fruit. Data secured in 1910 indicate that the size of the apples is possibly increased by the fertilizers, since the percentage of culls and seconds is a trifle higher in the check plats. The several current generalizations as to the effects of fertilizers on apples were not verified in this experiment. No change was noted in the color of the fruit, and all of the trees in the several plats have borne crops very uniform in maturity, keeping quality, texture, and flavor of apples. The diameter of the trees differed only within the range of variation in the several plats. In the nitrogen plats the foliage during the last season was greener than in other plats, and there was also a measurable effect of the nitrogen in the weight of the leaves. There is slight evidence that the trees on the nitrogen plats are making a greater annual growth of branches.

No detrimental influence attributed to the excessive amounts of fertilizers used is indicated.

An analysis of the soil made before the experiment was begun and here presented shows that at that time there was in the upper foot of soil enough nitrogen per acre to last mature apple trees 183 years, phosphoric acid for 295 years, and potash for 713 years. The conclusion is reached that tillage, cover crops, and good care have made available from this well-nigh inexhaustible supply all the plant food these trees needed. The author points out that whereas it may be necessary to fertilize some apple orchards in New York, such cases will be found on sandy and gravelly soils, on lands very subject to drought, on very shallow soils, and on soils quite devoid of humus. It is believed, however, that only a few of these soils will need a complete fertilizer.

As to the practical outcome of the experiment, it is pointed out to the fruit grower that his trees do not need fertilizers if they are vigorous and making a fair amount of new wood. If the trees are not vigorous, drainage, tillage, and the sanitary conditions should be looked to first and the fertilization afterwards if then found necessary. A plan is submitted for a fruit-grower's fertilizer experiment.

The packing of apples in boxes, C. S. Wilson (New York Cornell Sta. Bul. 298, pp. 681-693, figs. 10).—The use of the box package, so generally employed in packing and marketing western apples, is beginning in the East, and the aim of the present bulletin is to give such information as will enable the eastern growers to use the box pack more extensively. It discusses the box and box material, lining, layer and wrapping paper, the packing table, the box press, packing, and varieties suitable for packing in box or barrel. A plan and detailed specifications are given for the use and construction of a box press.

Utilization of the citrus fruits (Indian Agr., 36 (1911), No. 7, pp. 204-206).—In this article the general and fundamental principles underlying the manufacture of oils and essences from citrus fruits in Italy and France are given.
The culture and curing of vanilla in Mexico and in other countries, including suggestions for improving the industry, R. López y Parra (La Vainilla en Cultivo y Beneficio en la Republica Mexicana y en el Extranjero y Algunas Consideraciones Sobre el Perfeccionamiento de Este Rico Producto Agrícola. Mexico: Govt., 1911, pp. 78, pls. 5).—Part 1 of this pamphlet discusses the culture and curing of vanilla in Mexico, and part 2 deals with methods employed in other countries. Part 3 contains general considerations relative to the improvement of native methods of culture and curing.

Sweet pea studies, J. Craig and A. C. Beal (New York Cornell Sta. Bul. 301, pp. 749-763, pl. 1, fig. 1).—This comprises the results of field and forcing tests of sweet peas conducted cooperatively in 1900–10 by the Cornell Station and the National Sweet Pea Society of America. In the field tests 469 different varieties of Lathyrus odoratus from various sources were studied, together with a number of allied species and genera. The forcing tests conducted under glass for 2 seasons included 75 winter-flowering varieties. The majority of the varieties received for advance trial as well as those introduced in 1909 and in 1910 were true to type, although a number of unfixed or mixed stocks were noted. A list is given of the commended and highly commended varieties.

Autumn plantings of 3 varieties were compared with spring plantings of the same varieties. Starting with October 20, 1909, 5 successive plantings 10 days apart were made. Eight spring plantings were made from March 12 until the end of May. Four to 48 per cent of Mont Blanc, 5 to 52 per cent of King Edward, and 20 to 81 per cent of Countess Spencer came through the winter. The first 2 varieties gave the best results from the planting of November 10, and Countess Spencer did best from the earlier plantings. Plantings made either in fall or spring, when the surface of the ground was frozen, gave a low percentage of germination. The first 3 fall plantings of Mont Blanc came into bloom June 6 and the last on June 20. The fall plantings bloomed 2 weeks before the regular spring plantings of the same variety. Dry, hot weather brought all of the April plantings into bloom at the same time, the earlier plantings producing taller plants. On the later plantings the amount of bloom and length of stem was much reduced. The results indicate that white-seeded sweet peas should not be planted until the ground is warm, and that planting of the garden varieties after May 10 is hardly worth the trouble.

In the forcing tests varieties of the 3 winter-flowering groups, winter or Christmas flowering, Telemly, and the Engelmann group (Lathyrus odoratus praecox) were studied. A brief historical sketch of these groups is given. Only one variety tested proved to belong to the outdoor type. As to time of flowering the winter-flowering sweet peas were divided into 2 groups, the extra early flowering and the winter-flowering proper. The first group blooms about 3 weeks earlier but has smaller flowers and shorter stems than the latter. The varieties of the true winter-flowering group are crosses between some of the extra early group and the garden varieties of sweet peas. When studied along with 5 species of vetch (Vicia) no hybrid suspect between the vetch and Lathyrus odoratus was observed. The forcing varieties are classified according to color and discussed. A summary is also given of the leading varieties classified by color.

Our ornamental plants, P. F. F. Schulz (Unsere Zierpflanzen. Leipsic, 1909, pp. VIII+216, pls. 11, figs. 104).—The author here presents popular biological studies of a number of park, garden, and indoor ornamental plants, selected from the principal groups of the plant kingdom, including cryptogams, conifers, monocotyledons, and dicotyledons.
FORESTRY.

Light in relation to tree growth, R. Zon and H. S. Graves (U. S. Dept. Agr., Forest Serv. Bul. 92, pp. 59, figs. 10).—The aim of this bulletin is to bring together the principal facts relative to the part which light plays in the life of the forest and the different methods of measuring it. It is hoped that it may stimulate an interest to further research to determine more accurately the light requirements of our forest trees, especially by actual measurements of light in the forest.

The subject is discussed under the following general headings: Kinds of light, light intensities and tree growth, tolerance and intolerance of trees, factors influencing tolerance, measure of tolerance, methods of determining tolerance, and relative value of different methods.

A bibliography of the subject is appended.

[Forest plantations], C. B. Waldron (North Dakota Sta. Rpt. 1909, pp. 94, 95).—Among the deciduous trees in the different tree plantations of the station, the green and white ash, soft maple, hackberry, black walnut, and white birch made the most satisfactory growth. The catalpa has been discarded as wholly unsuited to the climate. The Norway maple seems to be too tender for general planting. The insect enemies of the cottonwood and Norway and Carolina poplars are increasing so as to discourage the general planting of these trees. Considerable difficulty is being experienced in establishing young coniferous trees.

[Report on forest plantings], C. B. Waldron (North Dakota Sta. Rpt. 1910, pp. 49, 51).—Brief notes are given relative to the behavior of a number of different species of trees as influenced by freezing and drought.

Uses of commercial woods of the United States.—I, Cedars, cypressess, and sequoias, W. L. Hall and H. Maxwell (U. S. Dept. Agr., Forest Serv. Bul. 95, pp. 62).—This is the first of a series of bulletins in which the aim will be to bring together in convenient form the available information on the uses of the different commercial woods. It is believed that the series will be of especial interest to lumbermen, those engaged in the wood-using industries, and foresters, as well as to instructors and students in forest schools.

The above species are considered separately, authentic information relative to the physical properties of each species being first presented, after which notes are given on the uses made of each wood from the earliest time, together with a discussion of their various uses at the present time. In addition to original data collected by the Forest Service, the subject matter has been gathered from many and widely scattered sources.

California tanbark oak (U. S. Dept. Agr., Forest Serv. Bul. 75, pp. 34, pls. 10).—The purpose of this bulletin is to show how the wood of the tanbark oak, which is now left in the forest to rot unused or to add fuel to forest fires, may be utilized and that a careful handling of the woodlands, coupled with conservative lumbering, ought to make the tanbark oak crop continuous and render this resource inexhaustible.

The bulletin consists of 3 portions. Part 1, Tanbark Oak and the Tanning Industry, by W. L. Jepson (pp. 5–23), discusses the development of the tanning industry in California, the silvical characteristics of the tanbark oak, the production of tanbark, the quality of the bark, prolonging the supply, tannin-extract process, and possibilities of utilizing the wood. Part 2, Utilization of the Wood of Tanbark Oak, by H. S. Betts (pp. 24–52), comprises results of tests relative to the strength, seasoning, and shrinkage qualities of tanbark oak, deals briefly with the various hardwoods used on the Coast, and suggests uses for tanbark oak. The appendix, Distribution of Tannin in Tanbark Oak,
by C. D. Mell (pp. 33, 34), contains a table indicating the location of tannin in the elements of pith, wood, and bark of a number of trees, together with brief directions for determining the distribution of tannin in plant tissues.

An investigation of the tannin content shows that tannin is present in the twigs of tanbark oak as well as in the older bark and that tannin extract could be made from the twigs and smaller branches, as in the case of the eastern chestnut (Castanea dentata). There is but little tannin in the wood-parenchyma elements of the heartwood, however, so that the tannin extract can not be got by chipping the wood and subjecting it to tanning-extract processes. Results of the timber test indicate that there is no good reason why tanbark oak should not be used in the Pacific Coast region for many, if not all, purposes for which eastern hardwoods are now imported. A commercial trial of this native oak as a substitute for eastern lumber is recommended.

"Colombian mahogany" (Cariniana pyriformis) (U. S. Dept Agr., Forest Serv. Circ. 185, pp. 16, figs. 11).—The purpose of this circular is to present to users of cabinet woods the distinguishing characteristics of one of the best imitation mahoganies now marketed. Its characteristics and its use as a substitute for true mahogany (Swietenia mahagoni) are described by G. B. Sudworth and C. D. Mell, and a description of its botanical characters is given by H. Pittier.

The authors are of the opinion that although Cariniana differs widely in its botanical and anatomical characters from true mahogany, its close superficial resemblance to mahogany and its physical properties at once distinguish it as a high-class cabinet wood, and there is no reason why it should not be employed under its own name for all purposes for which true mahogany is used.

Scrub pine (Pinus virginiana), W. D. Sterrett (U. S. Dept Agr., Forest Serv. Bul. 94, pp. 27, pl. 1).—In this bulletin the scrub pine is discussed relative to its nomenclature, distinguishing characteristics, distribution and occurrence, form and development, reproduction, enemies, characteristics of the wood, uses and market, advisability of forest management, purposes of management and rotation, sustained annual yield, new crops by natural reproduction, improvement thinnings, protection, extension, and the prevention of extension.

It is believed that this species, which is especially adapted to sterile soils and worn-out farm land, offers an important problem of wood-lot management in several eastern States, especially in Maryland and Virginia, where it has taken possession of many thousands of acres of idle farm land. The prevailing growth of the species is small, the wood being principally used for fuel, pulp wood, and charcoal. The extension of scrub-pine stands is not advocated, except where it is either impossible or impracticable to secure reproduction of more valuable species.

Relation of light chipping to the commercial yield of naval stores, C. H. Herry (U. S. Dept Agr., Forest Serv. Bul. 90, pp. 36, pls. 3, figs. 13).—In continuation of previous experiments by the Forest Service for the development of less destructive methods of turpentining (E. S. R., 17, p. 152), experiments were conducted in Florida during a 4-year period on a tract of about 25,000 trees of size suitable for turpentining to determine the yields as well as the effect on the vigor of the trees resulting from chippings of varying width, depth, and height.

The tract of timber was divided into 4 equal crops, including about 8,000 chipping faces each. Crop A was worked in a manner similar to that of surrounding commercial operations; the average depth of the cut in chipping, measuring from the inside of the bark, was 0.7 in. The only variation in crop B was a reduction of the chipping depth to 0.4 in., and in crop C a reduction in the height of the chipped surface by the end of the fourth year to 50 in. as compared
with 64.3 in., in crop A. On crop D the chipping was the same as in crop A, but the width of the unchipped surface was increased by raising the minimum diameter of trees to be turpentinized from 6 to 10 in., and the minimum diameter of trees to carry 2 chipping faces from 13 to 16 in. No tree in crop D carried more than 2 chipping faces. The shallow and narrow chippings as in crops B and C were also combined and tested for one season. The results of the investigation are summarized and discussed, and detailed yield tables are appended.

The total yield for the 4-year period from the standard crop A, based on corrected data, was 206,295 lbs. of dipped turpentine and 47,742 lbs. of scraped turpentine. Both shallow chipping and narrow chipping as in B and C gave a relatively small but valuable increase in yield of dip which was only partially offset by a reduced yield of scrape. Moreover, laboratory analyses showed that the dip from shallow-chipped trees in the second year was about 10 per cent richer in turpentine than the ordinary dip. The same increase is anticipated in the dip of narrow-chipped trees also. In both B and C there was evident at the end of the second year a heavy reduction in the loss from dead trees and faces abandoned because of dry face. It was also found that C could be profitably worked for a fifth year as a result of reducing the height of cut. The “light cupping” method employed in crop D gave a 35 per cent increase of dipped turpentine and a 13 per cent increase of scraped turpentine. In addition the timber was left in condition to be immediately worked again for a second 4-year period. In crop A a second working was entirely impracticable.

In the 4-year experiments the principal gain from improved methods has been found in the later years, due presumably to a decreased drain on the vigor of the trees. The combined narrow and shallow chipping, however, tried for only one year, showed an increased yield of dip of between 35 and 40 per cent in the single season, and on the basis of the 4-year results it is believed that this increase would have been maintained in subsequent seasons.

Acting on the results secured from Tschirch’s studies of resinous secretions and resin ducts, the report of which has been briefly noted (E. S. R., 18. p. 743), it has been found that the first dipping yields from the cup system of turpentinining may be considerably increased by making a regular chipping the full width of the face when the gutters are placed on the trees during the winter months. Vertical secondary resin ducts, which constitute the chief source of commercial crude turpentine, are thereby formed along the entire length of the cut, so that in the spring the first regular chipping will open the full number of these ducts instead of only a few ducts near the center of the face where preliminary winter chipping is not employed.

Taken as a whole the chipping experiments appear to demonstrate conclusively that the adoption by turpentine operators of the methods herein described will substantially increase the yield per crop of crude turpentine obtainable in a 4-year period; make possible the indefinite prolongation of the turpentine period; and cause far less sacrifice of merchantable timber. The Forest Service is to undertake continued turpentine experiments in the Choctawhatchee National Forest with the above aims in view.

Australian timber.—Its strength, durability, and identification, J. Mann (Melbourne, 1909, pp. XVI+148, figs. 19).—This treatise comprises a compilation of the data available prior to 1900 relative to the strength and durability of about 50 of the best-known engineering and construction timbers of Australia. The information was obtained at the engineering laboratories at the Sydney and Melbourne universities, government departments, and other reliable sources. Reports of subsequent timber tests in various Australian colonies have been noted (E. S. R., 19. p. 950; 20. p. 243; 21, p. 47).
Consumption of wood preservatives and quantity of wood treated in the United States in 1910, H. S. Sackett (U. S. Dept. Agr., Forest Serv. Circ. 186, pp. 4).—This is a statistical review based upon reports of 49 firms representing 71 treating plants, or 96 per cent of the plants in operation during the year.

The principal preservatives used, in the order named, are creosote, zinc chlorid, corrosive sublimate, and crude oil. In 1910 over 63 million gals. of creosote, of which 71 per cent was imported principally from England and Germany, and 16,802,552 lbs. of zinc chlorid, obtained from domestic sources, were used. The wood treated included crossties, piling, poles, paving blocks, construction timbers, cross arms, lumber, etc. The total material treated has increased from 68,228,299 cu. ft. in 1907 to 100,079,444 cu. ft. in 1910.

Grazing and floods: A study of conditions in the Manti National Forest, Utah, R. V. R. Reynolds (U. S. Dept. Agr., Forest Serv. Bul. 91, pp. 16, pls. 5, map 1).—The present study, which illustrates the harmful effect of overgrazing upon stream flow, is discussed under the following general headings: Grazing history, past floods, damage from floods, efforts to prevent damage, conditions affecting floods, including topography, soil, ground cover, rainfall and torrential run-off, and the future regulation of grazing.

It is concluded that the torrents that have devastated this region within the last 20 years have been caused primarily by overgrazing, and that they can be largely controlled, if not entirely eliminated, by restoration of the natural protective cover of shrubs and grasses.

The National Forest Manual: Trespass (U. S. Dept. Agr., Forest Serv., 1911, pp. 23).—This pamphlet, which constitutes a part of the Use Book (E. S. R., 22, p. 512), comprises regulations of the Secretary of Agriculture issued to take effect September 1, 1911, appertaining to trespass upon the National Forests, and instruction to forest officers thereunder.

DISEASES OF PLANTS.

[Mycological studies], H. L. Bolley (North Dakota Sta. Rpt. 1909, pp. 34–56, 62–66).—The results are given of investigations on diseases of wheat, flax, and potatoes, but mainly on wheat diseases caused by species of Colletotrichum, Macrosorum, Helminthosporium, and Fusarium which infect the stem, blades, and grain of the wheat and persist in the soil, thereby producing a species of wheat-sick soil.

Tables are given showing the results of various experiments with wheat and flax, including continuous cultures of wheat and flax in sand and in soil, and qualitative determinations of the fungi found in unsterilized and sterilized wheat plants. The bacteriological content of wheat seeds on an experimental plat and the examination of miscellaneous plant disease specimens are reported.

In the work with flax it was found that in addition to flax wilt there is a destructive canker of flax caused by a species of Colletotrichum, and also a disease of the flax bolls caused by species of Alternaria and Macrosorum. The flax canker seems to be confined largely to the western and northwestern dry regions of North Dakota. It is due to C. lini, and is characterized by a peculiar breaking off of the nearly mature flax plants at a point near the ground line. The disease is often found on new fields (virgin prairie sod) of flax, and is supposed to be caused by infection from native wild flax, or, more probably, by the use of internally infected seed, as flax seed are often found in which the seed leaves have cankers before the seed are matured. The canker disease is largely amenable to seed selection and seed treatment, but wilt-resistant varieties of flax are not immune to the canker.
A brief account is given of the work done during the past year on the herbarium and mycological survey, including a list of fungi from the State which have been added to the herbarium.

Report of botanist and plant pathologist, H. L. Bolley (North Dakota Sta. Rpt. 1910, pp. 43, 44, 46, 47).—The work, as in previous years, has been a study of the plants found resident in the soils of old cultivated lands and in the virgin soils, and of the micro-organisms that are found in the soils and upon cultivated plants on such soils. It is claimed that in many cases lands, which no longer produce the proper cereal crops, are not depleted of the plant-food constituents, but are contaminated with certain fungal organisms which attack the cultivated plants, destroying their roots, injuring the straw, and shriveling the grain. This is often the case during the years when otherwise the climatic and soil conditions are particularly favorable for a large growth of grain. It is also claimed that manures which are made in stables in which diseased straw has been used for bedding are very detrimental when spread without composting upon lands that are to raise the same kind of crop as that from which the bedding was made. In the work with bacteria and fungi of the soil it was found that many fungi ordinarily classed as saprophytes, especially Fusarium, Colletotrichum, Macrosomorium, Altenaria, and Helmimthosporium attack the roots, straw, and seeds of wheat, oats, barley, and flax.

The work so far on soils has been on the Red River Valley soils, and those taken from the demonstration farm at Rugby.

Reports on the diseases of economic plants in Germany for 1906, 1907, and 1908 (Ber. Landw. Reichsamte Innern [Germany] 1909, Nos. 13, pp. VII+179; 16, pp. VII+215; 1910, No. 18, pp. VIII+209).—These reports include discussions of the meteorological conditions, the influence of disease on the yield of certain crops, and various fungus, insect, and weed pests of field, forest, orchard, and truck crops during each of the years 1906, 1907, and 1908.

New observations on potato and grain diseases, J. Váňa (Wiener Landw. Ztg., 69 (1910), No. 95, p. 966).—The author claims to have found in the potato tissues attacked by leaf-roll disease not only the fungus Solanella rosae (E. S. R., 24, p. 151), but also 2 others, for which the names Sclerotinia solani n. sp., and Vermiculidaria dissepta n. sp., are proposed.

From experiments with pure cultures of the daisy schizomycete the following facts were obtained: The bacterium causing the primary tumors was found to occur also in the secondary tumors and sparingly in the tissues between the tumors. In this disease a cell stimulus begun in the primary tumors by the parasite is not able to propagate itself independently of the inciting organism. On the contrary, the bacterium and the tumor cells occur together both in the primary and secondary tumors, the one inside of the other.

The causative organism has not been seen in situ in the cells owing to inability to stain the organism without at the same time staining many confusing granules, but the indirect evidence of its presence is clearly proved by obtaining from the interior of the tumor tissues by the poured plate method the tumor-producing organism, Bacterium tumefaciens, even when stained sections of such tissues when studied under the microscope showed no evidence of the presence of the bacterium. It is claimed that deep-seated tumor strands are often found connecting primary and secondary tumors, wedging their way through the interior of stems and leaves after the manner of a foreign body. When the
primary tumor occurs on a stem and the secondary tumor on the leaves, the leaf traces and the loose cellular structure of the petioles are replaced by a firm greenish pseudopith or tumor tissue surrounded by a cylinder of wood, beyond which is a cambium and then a bark covered with cork.

Full details will appear in a later bulletin.

The rusts of grains in the United States, E. M. Freeman and E. C. Johnson (U. S. Dept. Agr., Bur. Plant Indus. Bull. 216, pp. 87, pl. 1, figs. 2).—This paper contains the results of recent investigations by the Office of Grain Investigations in cooperation with the Minnesota Agricultural Experiment Station in regard to the distribution, relationship, physiology, and life histories of the important grain rusts, and gives much new information on the biological forms of rust, vitality of successive uredo generations, wintering of the uredo generations, and climatology in relation to rust epidemics. Former experiments on rust are summarized and methods of selection and breeding of grains for rust resistance indicated.

The rusts discussed in this paper are as follows: Stem rust of wheat (Puccinia graminis tritici), leaf rust of wheat (P. rubigo-vera tritici), stem rust of oats (P. graminis avenae), crown rust of oats (P. coronata), stem rust of barley (P. graminis hordei), leaf rust of barley (P. simplex), stem rust of rye (P. graminis secalis), and leaf rust of rye (P. rubigo-vera secalis).

As a result of these investigations it is claimed that the morphological characteristics, life histories, and physiological specializations of parasitic fungi, including the rusts, may vary with the geographical distribution. The stem rusts of wheat, rye, oats, and barley, both in Europe and America, may produce the acacial stage on the barberry, but that this is necessary for continuous propagation from one season to the next has been disproved by experiments.

The acacial stage of the crown rusts of oats occurs in Europe on Rhamnus frangula and R. cathartica, and in the United States on R. lancoalata, R. caroliniana, and R. cathartica. The acacial stage of the leaf rust of rye occurs in Europe on Anchusa officinalis and Lycopus arvensis. The European and American forms are believed to be identical. The acacial stage of the leaf rust of barley is not known in Europe or America. This rust seems not to have been previously reported in this country.

The authors report the transference in the uredospore stage of the following rusts: “Stem rust of wheat (P. graminis tritici) from wheat to wheat, rye, and barley, but not to oats; from wheat to barley and then to wheat and rye; and from wheat to barley successively three times and then to oats. Stem rust of barley (P. graminis hordei) from barley to barley, oats, rye, and wheat; from barley to wheat and then to barley, wheat, oats, and rye; and from barley to rye, to barley, and then to wheat, oats, and rye. Stem rust of rye (P. graminis secalis) from rye to rye and barley from rye to barley and then to barley, oats, and rye; and from rye successively to barley, to barley, and to rye. Stem rust of oats (P. graminis avenae) from oats to oats and barley, but not to wheat or rye. Leaf rust of wheat (P. rubigo-vera tritici) from wheat to wheat, rye, and barley. Leaf rust of barley (P. simplex) from barley to barley only. Leaf rust of rye (P. rubigo-vera secalis) from rye to rye only. Leaf rust of oats (P. coronata) from oats to oats and barley, but not to wheat or rye.”

The following points as to the biologic forms of cereal rusts are emphasized: “(1) The stem rusts on wheat, barley, rye, and oats are undoubtedly biologic forms of the same species, Puccinia graminis; (2) these forms are not entirely confined to their hosts, but vary in range in part according to the host plants they have been recently inhabiting; (3) the leaf rusts on wheat and rye are more highly specialized than the corresponding stem rusts; (4) the stem rust
on barley has ordinarily the widest, while the leaf rusts on barley and rye have the most restricted, range; (5) under favorable conditions all the stem rusts can be carried successfully to the four cereals; (6) when rusts are transferred to ungenital hosts, if pustules are produced they are small and weak; (7) two biologic forms may inhabit the same cereals without being identical; (8) by gradual variation and adaptation to varying conditions a rust species widely distributed may form a number of strains or types, differing in physiological reactions; (9) the host plants exercise a strong influence not only on the physiological and biological relationships, but in some cases even on the morphology of the uredospore."

Many investigators hold that the acelial stage serves to reinvigorate the fungus, and to test this theory continuous cultural experiments with the uredospores of 6 different grain rusts were undertaken by the authors, and 52 successive uredo generations of each rust grown without the intervention of any other spore form and without any diminution in the vigor of the rust tested. It is claimed that the uredo stage of P. graminis and P. rubigo-sera live over the winter in the United States, as evidenced by work of previous investigators and confirmed by experiments cited in this bulletin. It is claimed that rusts in the uredo or acelial stages are present in different parts of the country at all times of the year, and by means of the wind or other agencies these spores may be carried from regions where they are abundant to places where the grain is in a receptive condition. It is claimed that the uniformly low temperature during the critical months of 1904 was a very important factor, if not the determining factor, for the rust epidemic of that year. The breeding of rust-resistant varieties of grain is the only method promising a successful combating of grain rusts so far as discovered.

A bibliography of 106 titles is appended.

Fusarium on cereals and its effect on germination and the wintering of the grain, L. Hilten and G. Insen (Landw. Jahrb. Bayern, I (1911), Nos. 1, pp. 20–60, figs. 8; 4, pp. 315–362, figs. 2; abs. in Deut. Landw. Presse, 38 (1911), No. 6, pp. 55–58, figs. 3).—The authors claim that the poor stands of winter grains often seen are due to attacks of Fusarium nivale which originate from seed-borne spores of the fungus.

Special attention is called to the results obtained from experiments on seed disinfection with a 1 per cent solution of corrosive sublimate, in which better germination, more vigorous growth, and greater yields were obtained than with the untreated grain on the check plats.

A cytological investigation of the grain rusts and the mycoplasma theory of Eriksson, F. Zsch (Sitzber. K. Akad. Wiss. [Vicuna], Math. Naturw. Kl., 119 (1910), I, No. 4, pp. 307–330; abs. in Bot. Centbl., 116 (1911), No. 1, pp. 17, 18; Centbl. Bakt. [etc.], 2. Abt., 30 (1911), No. 4–6, pp. 98–100).—A cytological study is reported of the leaves and stems of Secale affected by the uredospore mycelia of Puccinia graminis and P. glumae, in which the so-called plasmonuclei of Eriksson and also other smaller bodies were observed. The larger nuclenc-like bodies the author concludes are not real nuclei, but are probably haustoria in the cells.

Wheat rust (Depl. Agr. Egypt, Agr. Notes, 1911, No. 1, pp. 6).—In a discussion of rusts in general and of wheat rust in particular, the claim is made that only one species of wheat rust is known in Egypt, probably Puccinia graminis.

On the curly leaf disease of cotton, G. Kranzin (Pflanzenkr, 6 (1910), Nos. 9–10, pp. 129–145; 11–12, pp. 161–170).—A study is reported of the development of this disease, the alteration in the host produced by it, the condition of the various organs of the plant, and the influence of climate and soil on the disease.
The first symptom is the appearance in the field of areas in which the plants bear a more intense green color than normal, accompanied by a different position of the foliage. Later the leaves become discolored and curly.

From investigations conducted the author concludes that the disease is not of parasitic origin, nor due exclusively to soil or climatic conditions, but that it is probably the result of a too rapid and strong growth of the plants in connection with the attacks of the cicads.

Two recent important cabbage diseases of Ohio, T. F. Manns (Ohio Sta. Bul. 228, pp. 255-297, figs. 26).—A study is reported of "yellows" or Fusarium wilt and of blackleg or foot rot (Phoma oleracea) of cabbage, including symptoms of these diseases, methods of dissemination, losses caused by them and methods of control.

The Fusarium wilt is characterized by a yellowing of the lower, outer leaves, which later drop from the plant at the slightest touch. In older plants, sometimes stumps nearly full size may be seen that have shed all their leaves. Cross sections of infected stumps and roots, when not associated with bacterial action, show a light yellowing or browning of the vessels. If bacteria are also present, the vessels change to a dark brown or jet black.

No specific treatment is known for this wilt but seed treatment with formaldehyde, new seed beds each year, the use of only the most healthy and vigorous plants, immediate destruction of diseased plants if any should appear, rotation of crops, and the rejection of manures carrying infected cabbage litter are some of the means suggested for combating it.

The usual characteristic symptoms of blackleg or Phoma rot of the cabbage are described and comparisons made between the symptoms of this disease and the Fusarium wilt. In addition to the same methods as those recommended for combating the Fusarium wilt, a thorough spraying of the seed beds with Bordeaux mixture, particularly just before transplanting is advised, as one of the most active means of disseminating this disease is infection of healthy plants from a few diseased ones at the time of transplanting by the smearing of the spores on the healthy plants.

A brief bibliography is appended.

The Fusarium blight (wilt) and dry rot of the potato, T. F. Manns (Ohio Sta. Bul. 229, pp. 299-336, figs. 18).—This is a general discussion of this disease, including its history as a storage rot and as a field trouble, the cause of dry rot in storage, losses from using infected seed and from sick soil conditions, studies on the seed-potato condition in 1909 and 1910, culture work, and artificial inoculation work with sick soils in the greenhouse, factors which influence the progress and dissemination of the disease, early versus late planting, storage conditions for seed purposes, the length of crop rotations, care of refuse and infected material, field experiments in controlling the disease, effects of sprays on foliage, and remedial measures.

It was found that the dry-rot fungus (Fusarium oxysporum) of the potato is a common field trouble in Ohio, causing a blight and wilting of the crop and producing a sick soil condition in many potato districts. The field symptoms are a cessation of growth and a yellowing of the foliage with an upward and inward rolling of the leaves, accompanied by wilt during the heat of the day. The causative organism is carried within the tubers, which are the chief means of distributing the disease. This internal infection of the tuber is characterized by brown or black areas, usually in the fibrovascular ring.

The use of sound seed tubers, a 5 or 6 year crop rotation, especially with grass or grain crops, and the avoidance of infected barnyard manures as a fertilizer for potato lands are some of the suggestions given for the control of this disease.
The cause of gummosis of tobacco and experiments on its control, J. A. Hoxing (Meded. Deli-Proefstat. Medan, 5 (1911), No. 6, pp. 169-185).—This is a further study of this disease along lines similar to those followed in the first report (E. S. R., 24, p. 248), and includes infection experiments, a method of detecting the slime bacteria in the soil, and tests with chlorid of lime and potassium permanganate for controlling the disease.

A new fungus on dying apple trees, R. Laubert (Gartenflora, 60 (1911), No. 4, pp. 76-78, fig. 1).—The author describes as a new genus and species Pseudodiscula endogenospora, a semiparasitic fungus found on the bark of dying and dead young apple trees.

A new fungus on dying apple trees, R. Laubert (Gartenflora, 60 (1911), No. 6, pp. 133, 154).—A taxonomic discussion of the fungus noted above, in which the author decides that the fungus should be called Sclerophoma endogenospora.

Further researches on the development of ronchet of the grape, E. Panta
nelli (Atti R. Accad. Lincei, Rend. Cl. Fis., Mat. e Nat., 5. ser., 20 (1911), I, No. 8, pp. 575-583).—A general summary is given of the conditions of culture, soil, etc., which are associated with this disease of the grape, and the resistance of certain varieties of grapes to its attack is discussed.

The Sclerotinia (Botrytis) disease of the gooseberry, or die-back (Bd. Agr. and Fisheries [London], Leaflet 248, pp. 1-7, figs. 5).—The symptoms of this disease and remedies for its control are given. It may attack the main stem and base of the branches, the young wood of the current year’s growth, the leaves, and the berries.

The best method of controlling the disease is the prompt removal and burning of all dead bushes and branches. Heavy spraying with copper sulphate solution (4:100) just before the buds burst will kill the tufts of conidia which appear on the infected stems and branches, thus checking to some extent the spread of the disease, while spraying the foliage with Bordeaux mixture (8:8:100) will often prevent serious leaf infection.

A stem canker of Robusta and Quillou coffee, F. C. von Faber (Teysmannia, 21 (1910), No. 9, pp. 548-555).—A description is given of a new coffee disease which causes the leaves to become yellow and hang down against the stem, while dark-brown to black cankerous areas appear on the bark.

By microscopical examinations and culture tests the cause of the disease was found to be a fungus, for which the name Ascospora coffeae n. sp. is proposed. Infection experiments showed that the fungus does not attack sound, healthy trees, but enters through wounds in the bark.

The remedies suggested are the digging up and burning of the diseased plants.

Arrowroot diseases (Agr. News [Barbados], 10 (1911), No. 237, pp. 174, 175).—In an extract from a report of F. W. South on a “burning” of arrowroot in St. Vincent the characteristics of this disease and remedial measures are discussed.

The disease has been known on the island for a number of years and is widely distributed, appearing at places here and there in the fields, but spreading very slowly. The diseased plants have fewer leaves than healthy ones, and these are often rolled up and somewhat wilted, while the scale leaves of the rhizome are blackened throughout. The disease penetrates to the rhizome, forming small black spots, which increase in size until most of the surface becomes black. Dark-brown streaks ½ mm. in size run inward from the surface in a radial direction. A brown mycelium was found in narrow strands along the surfaces of the scale leaves, from which, under damp conditions, a white mycelium may often develop between the surfaces of the creeping stems and the inner surfaces of the scale leaves.
Cassava, tanna, yam, Indian corn, pigeon pea, plantain, banana, cacao seedlings, and bush plants are also attacked by this fungus. The systematic position of the fungus is not known.

The author advises the complete uprooting and burning of all diseased plants, followed by a thorough stirring of the soil and a 3-year planting with cotton before arrowroot is again planted in the soil.

Soft rot of ginger in the Rangpur District, eastern Bengal, W. McRae (Agr. Jour. India, 6 (1911), No. 2, pp. 139-146, pls. 2).—The symptoms of this disease, the damage done by it, and its causative organism are given, together with means for its control.

The disease produces a soft rot of the rhizomes, which is disseminated by planting diseased seed rhizomes, and is caused by the fungus *Pythium gracile*. The remedies suggested are the uprooting and burning of all diseased plants, including the roots and rhizomes, a 3-year rest for ginger land before replanting to this crop, the use of healthy seed, good drainage, and soil aeration.

The timber rot caused by *Lenzites sepiaria*, P. Spaulding (U. S. Dept. Agr., Bur. Plant Indus. Bul. 214, pp. 46, pls. 4, figs. 3).—This paper summarizes and brings up to date our knowledge concerning this serious wood-rotting fungus, contains new information concerning its life history derived from experiments in the laboratory and field, and gives methods for combating its ravages. The author discusses the economic importance of *L. sepiaria*, its distribution and hosts, and gives the characteristics of the fungus, its development, germination of spores, cultures, and inoculation experiments, describes the characteristics of the decayed wood, cites experiments which prove that *L. sepiaria* causes the decay attributed to it, and gives the factors governing the growth of wood-rotting fungi and the various methods used for preventing the decay caused by them. The paper closes with a brief summary of the extent of the damage done by this organism and its distribution. It is claimed that the *Lenzites* rot may be prevented or greatly retarded (1) by seasoning, (2) by floating, and (3) by chemical treatment of the timber with infiltrates which would be deleterious to fungus growth.

An extensive bibliography is appended.

Investigations on the employment of carbolinum compounds as fungicides, and their effects on plants. E. Mozz (Centbl. Bakt. [etc.], 2. Abt., 30 (1911), No. 7-12, pp. 204-232, pls. 6, fig. 1).—The results are reported of experiments on the use of carbolinum and various tar oils.

Very good results were obtained when the cankers of *Nectria ditissima* on the trunks of apple trees were treated with carbolinum, but a 1 per cent water solution of carbolinum protected the grape for only a short period against attacks of *Plasmopara viticola*. In plate culture tests with water-soluble carbolinisms it was found that *Sclerotinia fructigena*, *Botrytis cinerea*, and *Penicillium glaucum* were all checked in their development, especially *S. fructigena*, and this effect was more pronounced than that produced by copper sulphate solutions.

The fungicidal and bactericidal power of the light tar oils was found to be very small. The bactericidal action of tar oils seems to depend mainly on its phenol content, and those of a specific gravity of 1.023 were most effective as fungicides and bactericides. Plant tissues were much injured by the action of phenols. The vapor of tar oils, especially of the lighter ones, was found to act injuriously on plants, and a 1 per cent water solution of tar oil in most instances injured the foliage of trees. The use of carbolinum paints on the trunks of trees showed no injurious effects. The spring treatment of wounds with carbolinum preparations was found to be injurious, often causing an enlargement of the wounded area and a slow healing of the wound.
Tar oils containing phenol, or, still better, the crude carbolic acid itself, were found to be very effective as herbicides when used in a 15 per cent solution.

The first injurious effects of soils containing carbolineum solutions were observed when the soil contained 0.02 gm. of water-soluble carbolineum per pot of 200 gm. of earth, and the injury manifested itself by a diminished growth of the plant. On grapevines treated with carbolineum the first injury was observed from a water-soluble solution of 2 gm. per pot. The soil disinfection with carbolineum compounds was greatest when the crude tar oil itself was used, but was injurious to plant production if used on the soil shortly before planting. If, however, the soil was treated several months before the planting, the yield was increased.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Our grosbeaks and their value to agriculture, W. L. McAtee (U. S. Dept. Agr., Farmers' Bul. 456, pp. 14, figs. 3).—Seven kinds of finches, commonly known as grosbeaks, are said to summer within the United States. Two of them live mainly in cold or mountainous areas and have little to do with farms or with the insects that prey on crops. The other 5, namely, the rose-breasted grosbeak or potato-bug bird, the cardinal or redbird, the black-headed grosbeak or western grosbeak, the blue grosbeak or blue pop, and the gray grosbeak or parrotbill, live largely in agricultural regions and secure most of their food about cultivated lands. All 5 feed to some extent upon crops, but only one does appreciable harm. On the other hand, all perform invaluable service in destroying certain of our worst insect pests.

The author briefly describes the food habits, a fuller account of which has been previously noted (E. S. R., 19, p. 958), and the means of preventing them from damaging crops, and of attracting and protecting them.

"Present investigations prove that the services of grosbeaks in destroying insect pests are invaluable. Each kind pays special attention to certain pests which if unchecked would cause enormous losses. Few of our birds are to be credited with more good and with fewer evil deeds than the grosbeaks, and none more clearly deserve protection by the practical farmer."

A brief report on the work now being prosecuted by some economic entomologists in the state universities, agricultural colleges, and experiment stations of the United States, T. J. Headlee (Jour. Econ. Ent., 4 (1911), No. 1, pp. 35-37).—A report presented at the twenty-third annual meeting of the American Association of Economic Entomologists.

Report of the entomologist of the Arizona Horticultural Commission for the year ending June 29, 1910, A. W. Morrill (Ariz. Hort. Com. Ann. Rpt., 2 (1910), pp. 8-15).—The insects, the occurrence of which is briefly noted, are the codling moth, woolly aphids, bryobia mite, date-palm scales, grasshoppers, orange thrips, ants, and soft scale. Inspection work and insect control are also briefly considered.

Sixth annual report of the state entomologist of the State of Maine, E. F. Hitchens (Ann. Rept. State Ent. Maine, 6 (1910), pp. 39, pls. 2).—The author reports briefly upon the occurrence of some of the more important insects of the year and upon the work of nursery inspection. A report by E. E. Philbrook, special field agent in charge of the gypsy moth work, is appended.

Injurious insects, C. B. Waldron (North Dakota Sta. Rpt. 1910, pp. 51, 52).—Grasshoppers, the only pests that caused serious injury during 1910, were the source in a few instances of total losses of from 80 to 100 acres of grain. Meadows and pastures suffered severely and fruit trees and shrubs to a considerable extent. Losses to garden crops were also very common. The de-
struction was caused almost wholly by 3 native species, namely, the two-striped locust \( (Melanoplus vivitattus) \), the red-legged locust \( (M. femur-rubrum) \), and the lesser migratory locust \( (M. atlantis) \).

Papers on insects injurious to citrus and other subtropical fruits.—The orange thrips: A report of progress for the years 1909 and 1910, P. R. Jones and J. R. Horton (U. S. Dept. Agr., Ent. Ext. Bull. 99, pt. 1, pp. 16, pls. 3, figs. 2).—This is a report of studies of the orange thrips \( (Euthrips citri) \) in continuation of those of Moulton previously noted (E. S. R., 20, p. 956).

This species is thought to be a native of the Sierra Nevada foothills or the adjoining plains of the southern San Joaquin Valley. It is distributed throughout the entire orange belt of the San Joaquin Valley and has been collected in several places in Southern California and at Phoenix, Ariz., by the senior author. The infestation in Arizona embraces orange groves in the Salt River Valley surrounding Phoenix. It has also been reported from Hermosillo, Sonora Province, Mexico. Attention is called to the fact that while \( E. occidentalis \) also is occasionally found upon citrus trees, as reported by Coit (E. S. R., 21, p. 44), it rarely causes serious injury.

In addition to citrus, the authors have taken the orange thrips from pomegranate \( (Punica granatum) \), varieties of European grape, California pepper tree \( (Schinus molle) \), umbrella tree, pear, apricot, peach, varieties of European plum, willow \( (Salix sp.) \), dock \( (Rumex sp.) \), purslane \( (Portulaca oleracea) \), olive, red raspberry, rose, and \( Solanum \) sp.

Technical descriptions are given of the egg, larva, and pupa. The orange thrips passes the winter in the adult state, and it is generally the adult form which first becomes conspicuous upon the orange trees in the spring. Examinations for eggs revealed the fact that most of them are placed in the new, tender growth, being inserted into both upper and lower leaf surfaces and also in the shoots. They are also placed in the receptacles of the blossoms after the petals have fallen and in young fruit and fruit stems. The relative abundance of the thrips on various food plants during the season is diagrammatically illustrated. The life cycle obtained by adding the average lengths of egg, larval, and pupal stages and allowing 3 days for the preoviposition period was found to be 18.68 days from May to August, 1909, while for the months from April to August, 1910, the period was 23 days. "Although the number of generations in a season has not been definitely observed, there are probably 4 and a partial fifth during the period of May to July, inclusive, and 1 generation in each of the months of March, April, August, September, and October, making in all a possibility of 8 to 10 generations for the season." Its ability to run, leap, and fly is much greater than that of any other thrips so far observed by the authors, who have frequently seen adults fly from one tree to another 20 ft. or more distant.

The spraying experiments here reported show that the pest can be controlled by 4 sprayings of lime-sulphur solution combined with a commercial tobacco extract, which should be applied when the thrips become sufficiently numerous. Three applications should be made in the spring months to save the fruit and spring growths from injury, and one in the fall to lessen the feeding injury to the fall growth of the orange trees. The 3 spring applications should be made as follows: The first just after most of the petals have fallen; the second, from 10 to 14 days after the first; and the third, from 3 to 4 weeks from the time of the second treatment. The spraying solution should consist of lime-sulphur \( (33^\circ \text{B.}) \) 1:75 and blackleaf tobacco extract \( (2\% \text{ cent nicotin}) \) 1:100; or, using blackleaf "40" (40 per cent nicotin) tobacco extract 1:1,800. If lime-sulphur of 30° B. is used, the formula would be lime-sulphur 1:86 and blackleaf tobacco extract 1:100; or blackleaf tobacco extract "40" (40 per cent nicotin) 1:1,800.
EXPERIMENT STATION RECORD.

nicotin) 1:1,800. From 2 to 8 gals. of this combination spray should be applied per tree, at a high pressure, and in a very thorough manner, as only thrips that are hit will be killed. The spraying experiments have shown that 3 thorough applications at the proper times result in from 20 per cent to 60 per cent more "fancy" fruit in the sprayed as compared with the unsprayed blocks.

Occurrence of Euthrips pyri in New York State, P. J. Parrott (Science, n. ser., 31 (1911), No. 864, p. 94).—The author reports the discovery of Euthrips pyri in New York orchards. During the spring of 1911 specimens of injured blossom clusters were received from Germantown and other localities along the Hudson River. The peculiar blighting of pear blossoms in various localities in the State during the past several years, which has been attended by considerable loss in the fruit yields, is thought to have been due to this pest.

Tests which have been conducted indicate that the thrips may be effectively combated by slight changes in the scheme of spraying which the author is encouraging growers to adopt for the control of the pear psylla.

The pear psylla, P. J. Parrott (West. N. Y. Hort. Soc. Proc., 56 (1911), pp. 73-82, figs. 6).—The year 1910 is reported to have been notable for the overwhelming invasion of pear orchards in western New York by this insect. By midsummer the foliage of most of the pear orchards was scanty, blackened, and badly discolored. In some instances the fruit dropped and failed to mature, thus reducing the yield.

Observations made at Lockport showed the adults to be appearing on March 26, eggs being laid on April 2 and hatched on April 10. On the basis of observations and experiments, the author considers the most practical preventive and remedial measures to consist of (1) clean culture, (2) removal and destruction of the bark of trees on which the pest is hibernating, (3) spraying of trunks and large limbs with miscible kerosene emulsion, or whale-oil soap to destroy those that are hibernating, (4) spraying of trees just before the leaves appear with lime-sulphur wash to destroy eggs, and (5) spraying of trees with kerosene emulsion, whale-oil soap, or tobacco extract at summer strengths to kill newly hatched nymphs.

The cabbage aphids (Aphis brassicace), G. W. Herrick and J. W. Hungate (New York Cornell Sta. Bul. 300, pp. 717-736, pls. 4, figs. 5).—The cabbage aphids, which is of European origin, found its way into this country more than a century ago and is now a pest throughout the United States, having been described in the bulletins of 23 state experiment stations. In 1890, 1903, and 1908 it was very numerous, widespread, and destructive in New York State, the year 1903 being particularly an aphid year. More inquiries were received by the Cornell Station in 1909 and 1910 regarding this aphid than any other insect pest.

"Aside from cabbages, this aphid attacks and injures turnips, cauliflowers, Brussels sprouts, rape, kohlrabi, collard, kale, and broccoli. It is often found on the seed stalks of radish, and it frequently destroys seed stalks of cabbage. In addition to these, it has been found on shepherd's purse, field cress (Isatis tinctoria), white mustard (Brassica alba), charlock (B. [Sinapis] arvensis), black mustard (B. nigra), wild radish (Raphanus raphanistrum), B. fructulosa, B. adpressa, and Diplotaaxis tenuifolia." The authors' observations lead them to conclude that while it is possible that this aphid may have an alternate food plant, it does not always depend upon it.

Studies of its life history, which are reported in detail, include technical descriptions of the several forms. The authors found that there were 50 generations in approximately 1 year with an average for each generation of 128 days. There may be 16 generations from March 31 to October 2, and all of these may be born in the field in some seasons. It was found that 1 female
may bear 50, 60, or even 70 young, and each of these in turn may bear as many young, and so on throughout the season. The winter is usually passed in the egg stage.

At least 2 species of primary parasites, *Xystus brassicae* and *Aphidius (Diaeretus) picus*, are abundant in New York State. Other insects, reared from the bodies of aphids on cabbage leaves, were *Asaphes rugipes*, supposed to be a hyperparasite, and *Pachyneuron micans*. Two species of lady beetles, namely, *Adalia bipunctata* and *Hippodamia convergens*, were very abundant in 1910 and did effective work in destroying the aphids. The larvae of at least 4 species of *Syrophus* flies, namely, *Sphaerophoria cynlindrica*, *Allograpta obliqua*, *Syrophus americana*, and *S. ribesii*, were seen feeding on the aphids in the State.

Methods of control include the destruction of cabbage leaves and stalks, dipping of seed-bed plants or fumigation of seed beds with tobacco paper, and the spraying of plants in the field. Seed-bed plants were dipped in a homemade fish-oil soap made in the following proportions: Caustic soda 1½ lbs., water 1½ qts., and fish oil 5½ lbs. A 1:8 solution of this soap is said to have killed every aphid hit. In experiments with Leggett's Anchor Brand of whale-oil soap, 1:8 solutions gave equally good results, but weaker solutions of 1:10 and 1:15 were inferior to like solutions of the fish-oil soap. But few aphids were killed when plants were dipped in Blackleaf 1:64.

"A series of plants dipped in solutions of lime-sulphur, 32.5° B. in the proportions of 1:40 and 1:30, were quite badly burned in every case and only a small percentage of aphids was killed. The tendency of the lime-sulphur to run off the leaves without apparently touching the aphids was almost as marked as in the case of the tobacco extract. In . . . laboratory experiments in which individual plants well infested with lice were sprayed with solutions of lime-sulphur at the rate of 1:20, 1:15, and 1:10 of water, respectively, the plants were injured in every case and but 55 to 65 per cent of the aphids was killed."

In tests made of Nico-fume, 1 paper was used to every 25 sq. ft. of surface, a smoke-proof muslin attached to a skeleton frame 1 ft. high being used as a cover. The aphids on plants fumigated in this way for 30 minutes were killed and the plants not injured.

It was found that the homemade soap solutions did not kill the immature stages of the parasites when protected by the dried skins of the dead aphids.

The authors estimate that cabbages in the field can be sprayed with a power sprayer at a cost not to exceed 75 cts. per acre. It was found in field experiments that the cost with a knapsack sprayer was a fraction over $2.15 per acre, including labor and material when the fish-oil soap was used and could be purchased at 3½ cts. per pound.

A list of the more important articles on this aphid is appended.

**The cabbage aphid, *Aphis brassicae*, G. W. Herrick (Jour. Econ. Ent., 4 (1911), No. 2, pp. 219–224).**—The data here presented are included in the article noted above.

**White flies injurious to citrus in Florida, A. W. Morrill and E. A. Back (U. S. Dept. Agr., Bur. Ent. Bul. 92, pp. 109, pls. 10, figs. 19).**—This bulletin presents the principal results of studies of the life history, seasonal history, habits, food-plant relationships, etc., of the citrus white fly (*Aleyrodes citri*) and the cloudy-winged white fly (*A. multiplica*).

A list is given of 12 species and one subspecies of *Aleyrodidae* known to breed upon citrus, together with their distribution and food-plant records. Of these, *A. citri*, *A. giffardi*, *A. howardi*, and *A. multiplica* are known to be orange pests or capable of becoming orange pests. *A. floridensis*, *A. mori*, *A. mori arizonensis*, and *Paralyrodes persea* apparently are not likely to cause injury to citrus, while the 5 remaining are doubtful in this respect.
The origin of the citrus white fly is by circumstances quite definitely indicated as Asiatic. In addition to Florida, where about 40 per cent of the orange groves of the State are estimated by the authors to be infested, it occurs in South Carolina, southern Georgia, Alabama, Mississippi, Louisiana, Texas, and California (in which State it was first discovered in 1907). Outside of the United States it is known to occur in Mexico, Brazil, Chile, China, Japan, and India (Northwestern Himalayas). So far as known it does not occur in Cuba.

It is estimated that this species was the source of total loss in value of fruit of $606,700 of the crop of 1907–8 and that the crop of 1908–9 was affected to the extent of $750,000.

The authors find that A. citri shows a greater degree of adaptation to the umbrella tree than to citrus, that the adults are so strongly attracted by growing leaves of umbrella trees that under certain conditions with umbrella and citrus trees growing side by side more adults collect on 3 or 4 umbrella leaves than are present on an entire citrus tree of medium size.

The eggs hatch in from 8 to 24 days, according to the season. "During ordinary summer weather from 75 to 100 per cent hatch on the tenth to twelfth day. Infertile eggs hatch as readily as fertile eggs and produce adults of the male sex only. After hatching, the young larva actively crawls about for several hours, when it ceases to crawl, settles upon the underside of the leaf, and begins to feed by sucking the plant juices. It molts three times before becoming a pupa. After the first molt the legs become vestigial; hence thereafter it is impossible for it to change materially its location upon the leaf. Larval life averages in length from 23 to 30 days. The pupa closely resembles the grown larva and requires from 13 to 304 days for development. The adult fly has an average life of about 10 days, although several females have been known to live 27 days. Females may begin depositing eggs as soon as 6 hours after emergence and continue ovipositing throughout life. The maximum egg-laying capacity is about 250 eggs, although 150 more nearly represents the number laid under grove conditions. Unfertilized females deposit as many eggs as fertile females. The entire life cycle from egg to adult requires from 41 to 333 days; the variation in the number of days required from eggs laid on the same leaf on the same day is very remarkable." This variation is absolutely independent of both temperature and humidity influences. The sums of effective temperatures required for the minimum duration of immature stages for individuals developing from eggs deposited between February 23 and August 8 vary from 1,641 to 2,153°, with an average of 1,846°, which may be regarded as very nearly the normal for minimum development up to the time when all individuals winter over as pupae. During the course of the year the fly may pass through a minimum of 2 generations and a maximum of 6 generations. The generation started by the few adults that emerge during the winter is entirely dependent upon weather conditions and may or may not occur. Each generation except those started after the middle of August is more or less distinctly two-brooded.

"Specimens of the cloudy-winged white fly (eggs, larva, and pupa) in the collection of the Bureau of Entomology show that this species occurred on oranges in the United States as early as 1889. The records in connection with the specimens show that it was collected in Mississippi and North Carolina in 1889, in Louisiana in 1890, and in Florida in 1895. Outside of the United States it is known to occur only in Cuba. Its introduction into the United States from Cuba does not seem as probable as its introduction into Cuba from the United States. Its food-plant differences and adaptations are such that orange trees are not as a rule subject to as heavy infestations as by the citrus white fly, although with grapefruit trees this situation is usually reversed. Most important as a factor limiting the injury from the cloudy-winged white fly is that
when both occur in an orange grove the citrus white fly almost invariably pre-
dominates and the cloudy-winged white fly assumes a position of comparative
insignificance.

The authors estimate that there are about 5 per cent of the orange and tan-
gerine groves in Florida infested by the cloudy-winged white fly that are not
also infested by the citrus white fly, and that there are in addition 1 per cent
of orange and tangerine groves infested by both species, but in which the citrus
white fly has not as yet attained injurious abundance. The average damage
from the cloudy-winged white fly is estimated at about 10 to 15 per cent lower
for oranges where that species alone infests the grove than where the citrus
white fly is the species concerned. For injury to grapefruit the authors con-
sider 25 per cent a fair estimate of the injury by the cloudy-winged white fly
as compared with about 10 or 15 per cent by the citrus white fly. The total
loss in Florida due to the cloudy-winged white fly is estimated by the authors
at between $100,000 and $125,000 per annum at the present time. So far as
known at the time of writing the cloudy-winged white fly occurred in 12 coun-
ties in Florida. Outside of Florida, it has been collected at New Orleans and
Baton Rouge, La., Pass Christian, Miss., and Raleigh, N. C. It appeared at
Bakersfield, Cal., in 1907, but appears to have been eradicated from the State.
It is not known to breed upon any other plant than citrus in Florida, but has
been discovered infesting rubber trees (Ficus nitida) growing in the green-
houses in Audubon Park, New Orleans.

The egg of the cloudy-winged white fly differs from that of the citrus white
fly in that it is not greenish-yellow and highly polished, but bluish or grayish
black and roughened by a film of wax arranged in a hexagonal pattern. The
duration of the egg stage is in general slightly longer than that of A. citri. As
the bulk of the eggs hatch from 1 to 10 days later, a slightly higher number of
degrees of accumulated effective temperature are necessary, and hatching is
more evenly distributed though not always extending over a larger number of
days. It has been found that virgin females of this species will deposit eggs
and that these readily hatch and produce healthy larvae.

The larva of A. nubifera are slower in maturing than those of A. citri. While
this difference is not so pronounced during the warmer months of the
year, the total average number of days being 25.9 and 23.1, respectively, during
the cooler months it is very striking, the total average number of days then
being 56.7 for A. nubifera, as compared with 39.4 for A. citri. In other re-
spects the duration of the larval instars for the 2 species is the same. Little
difference exists between the length of the pupal stages. It is estimated that
the maximum egg-laying capacity of A. nubifera is not far from 200.

A note on the Indian enemies of Aleyrodes citri, with description of a
new species of Prospaltella, L. O. Howard (Jour. Econ. Ent., 4 (1911), No. 1,
pp. 130-132).—Investigations made in India by an agent of the Bureau of
Entomology of this Department have shown that the citrus white fly (A. citri)
occurs in that country upon citrus plants practically wherever they grow, even
in localities where citrus grows in the jungle. It was found to be under con-
trol, however, the concomitant smut fungus being discovered in but one instance.
The natural enemies discovered, and supposed to be responsible for holding
this pest in check, are Egerita webberi, the smut fungus that occurs in
Florida; two coccinellid beetles (Verania cardoni and Cryptognatha flavescens);
and the aphelinid parasite Prospaltella tahorensis, here described as
new to science.

Notes on the biology of the cochylis (Cochylis ambiguella) and eudemis
(Polychrosis botran) moths, M. F. Picard (Compt. Rend. Acad. Sci. [Paris],
152 (1911), No. 25, pp. 1792-1794).—This article consists of brief notes on the
appearance of adults in spring in the Department of Herault, and their feeding habits and reproductive capacity.

Annual reports of the Royal Sericultural Station, Padua (Ann. R. Staz. Bacol. Padova, 37 (1910), pp. 117, figs. 6; 38 (1911), pp. 160, pls. 6, figs. 6).—These reports contain papers by E. Verson and E. Bisson and by E. Quajat on the silkworm and silk culture. Bibliographies of the literature relating to sericulture that were published during the years 1908-9 (pp. 99-117) and 1909-10 (pp. 135-159), respectively, and here presented, were prepared by E. Bisson.

Illustrations of diurnal Lepidoptera, A. G. Weeks, Jr. (Boston, 1905, vol. 1, pp. XII+117, pls. 45; 1911, vol. 2, pp. XVI+37, pls. 21).—Volume 1 of this work consists of colored plates and descriptions of 51 species, largely from Bolivia, which the author has found to be new to science. An account by W. J. Gerhard of a 60 weeks' collecting trip in that country is incorporated in the work.

Volume 2 is confined to descriptions and colored plates of species taken in the neighborhood of Suapure River in Venezuela. A list of the scientific writings of W. H. Edwards is included.

The importation into the United States of the parasites of the gipsy moth and the brown-tail moth: A report of progress with some consideration of previous and concurrent efforts of this kind, L. O. Howard and W. F. Fiske (U. S. Dept. Agr., Bur. Ent. Bul. 91, pp. 312, pls. 28, figs. 74).—In the first part of this detailed report the authors consider previous work in the practical handling of natural enemies of injurious insects, early ideas on introducing the natural enemies of the gipsy moth, the circumstances which brought about the actual beginning of the work, the known and recorded parasites of the gipsy moth and brown-tail moth, establishment and dispersion of the newly introduced parasites, disease as a factor in the natural control of the gipsy and brown-tail moths, studies in the parasitism of native insects, and parasitism as a factor in insect control.

Attention is next given (pp. 109-131) to the gipsy moth, its rate of increase in New England, the amount of additional control necessary to check its increase in America, the extent to which it is controlled through parasitism abroad, and the sequence of its parasites in Europe. Then follow accounts (pp. 132-168) of the brown-tail moth and its parasites in Europe, parasitism of the gipsy and brown-tail moths in America, the importation and handling of parasite material, and the quantity and localities from which the parasite material has been received.

The remainder of the bulletin is largely devoted to specific consideration of the various parasites and hyperparasites of the 2 moths. The bulletin closes with a summarized account of the present status of the introduced parasites and of developments of the year 1910.

Formalin poison for flies, R. I. Smith (Bull. N. C. Bd. Health, 26 (1911), No. 2, p. 71).—The author has used milk with formalin, at the rate of 16 oz. of equal parts milk and water to 1 oz. of formalin, with excellent results. This mixture is said to attract flies much better than when the formalin is used in sweetened water.

Control of the apple maggot by picking up drops, W. C. O’Kane (Jour. Econ. Ent., 4 (1911), No. 2, pp. 173-179, figs. 4).—A more detailed account of the author’s investigation on the subject than that previously noted (E. S. R., 25, p. 356).

The apple maggot or “railroad worm,” W. C. O’Kane (New Hampshire Sta. Circ. 14, pp. 4, figs. 2).—This circular, based on investigations previously noted (E. S. R., 25, p. 356), calls attention to the methods by which the infestation of the apple maggot can be checked.
Contamination of the fly with poliomyelitis virus, S. Flexner and P. F. Clark (Jour. Amer. Med. Assoc., 56 (1911), No. 23, pp. 1777, 1718)._—Experiments conducted with a view to determining whether or not the house fly carries the infection of this disease are here reported. They "show that flies contaminated with the virus of poliomyelitis harbor the virus in a living and infectious state for at least forty-eight hours. They do not show that this is the limit of the period of survival, and they throw no light on the question whether the virus is retained merely as a superficial contamination or whether it can survive in the gastro-intestinal tract. Experiments relating to these points are in progress."

The mosquitoes, R. Blanchard (Les Moustiques.—Histoire Naturelle et Médicale. Paris, 1905, pp. XIII+673, table 1, figs. 316).—The 7 chapters of this work take up the subject as follows: (1) Description and place of mosquitoes in zoological classification (pp. 1-43), (2) anatomy (pp. 44-67), (3) habits and metamorphosis (pp. 68-135), (4) systematic study, with descriptions of the genera and species (pp. 136-430), (5) mosquitoes as pathogenic agents (pp. 431-548), (6) general prophylaxis (pp. 549-590), and (7) the collection and study of mosquitoes, including means of preparation and preservation (pp. 600-618).

The species and genera recently described are listed in an appendix (pp. 619-635). The work also includes a bibliography of 25 pages and an index.

Papers on deciduous fruit insects and insecticides.—Vineyard spraying experiments against the rose-chafers in the Lake Erie Valley, F. Johnson (U. S. Dept. Agr., Bur. Ent. Bul. 97, pt. 3, pp. 53-64, pls. 4, figs. 6).—Following a brief introduction and account of the habits of the adult and larva, the author considers remedial measures at some length, particularly spraying experiments conducted at Northeast, Pa., and observations of spraying operations at other points in the Lake Erie Valley. He states that his observations with the use of a sweetened arsenical do not justify the recommendation of its general use. Experiments during the season of 1910 indicate that a very thorough application of arsenate of lead when the beetles appear, just before the blossoms open, will reduce its destructiveness to the extent that a profitable crop of fruit can be secured even in vineyard areas where this insect abounds in destructive numbers.

The lesser grain-borer (Rhizopertha dominica) (pp. 29-47).—This beetle is cosmopolitan, attacks different cereals and several other substances, and is of considerable economic importance, especially in warm and tropical regions. It has already obtained a footing in this country and is frequently brought here from outside sources in stored cereals and other seeds and similar material. So far as known it appears to prefer grain to other dry products but shows an inclination to be omnivorous, feeding also upon drugs and boring into the wood of packing boxes and casks.

The species was described by Fabricius in 1792 from specimens collected in South America. According to published records, it is, or at least was for years, most injurious in India; it is thought to be safe to assume that it came originally from India or from some adjacent tropical country. In Europe it is seldom found outside of London, Trieste, and a few other large seaports. Its abundance in London is attributed to the large quantities of grain that were brought from India to that port. In the United States it seems to be well established in some southern ports but to have a more or less insecure footing northward, except in large seaports, like New York City. A list of localities
from which it has been reported in this country includes New York City, Brooklyn, N. Y., Washington, D. C., Chicago, Ill., Keokuk, Iowa, Charleston, S. C., Atlantic County, N. J., Philadelphia, Pa., Arizona, and Canada. It has also been recorded from Vera Cruz, Mexico, Belize, Honduras, Cuba, Hawaii, Madeira, and Algeria.

In experiments with carbon bisulphid and hydrocyanic-acid gas from sodium cyanid, by D. K. McMillan; with hydrocyanic-acid gas from sodium cyanid, by M. M. High; and with carbon bisulphid, by Messrs. Popoone and Jones and the author, it was found that the lesser grain-borer possesses less resistant power to both gases than do most other stored-product insects; that fumigations in low temperatures, and especially below 50° F., are practically ineffective unless an excessively large amount of bisulphid of carbon or of a cyanid be used; and that it is still more desirable that from 48 hours to 3 days be the length of exposure in order to kill all insects in even tight inclosures. One experiment showed that even with 10 lbs. of bisulphid of carbon to 1,000 cu. ft. of space in a tight receptacle only a very small percentage of grain insects were killed in an exposure of 24 hours and with a temperature of about 48° F., and another that even with 20 lbs. of carbon bisulphid to 1,000 cu. ft., or 10 times what may now be accepted as a standard, only 75 per cent of the insects present were destroyed in a 24-hour exposure.

The author concludes that it may be safely assumed that under ordinary conditions, in temperatures between 65 and 75° F., 1½ lbs. of bisulphid of carbon to 1,000 cu. ft. of air space is insufficient even for 48 hours' exposure, and that as a general standard 2 lbs. to 1,000 cu. ft. for 48 hours or more, or until the odor of the gas has become entirely dissipated, may be adopted.

A bibliography of 21 titles is appended.

The larger grain-borer (Dinoderus truncatus) (pp. 48-52).—So far as the author knows, this species has never found permanent lodgment in the United States, but is apt to be introduced into tropical Texas as well as elsewhere. It is tropical, and though a general feeder, at least in its adult stage, is by virtue of its large size apparently restricted in cereals to maize.

This beetle was first described in 1878 from specimens accidentally found in California. It was also accidentally brought to this country with corn for exhibition in the Mexican section of the New Orleans Exposition in 1885, and in 1893 specimens were obtained in corn and edible roots from the Mexican and Guatemalan exhibits at the World's Columbian Exposition, at Chicago. It has since been received in stored corn from Tlaxiaco, State of Oaxaca, and from Parral, Province of Chihuahua, Mexico.

The author finds that the pupal stage varies from about 4½ days in the very hottest weather to 6 days in a little cooler weather during June and July, while in October the pupal period lasted 12 days, from October 17 to 29. The entire life cycle from the placing of beetles in corn until the issuance of the new generation occupied 45 days, from August 25 to October 9.

A bibliography of 5 titles is included.

The bulb mite, F. WINDLE (Jour. Econ. Ent., 4 (1911), No. 1, pp. 127, 128).—The bulb mite Rhizoglyphus hyaoithi (echinopus), also known as the "Eucharis Mite," has been found to be the source of considerable injury to bulbs imported from France, Holland, and Japan.

The taxonomic value of the microscopic structure of the stigmatic plates in the tick genus Dermacentor, C. W. STILES (Pub. Health and Mar. Hosp. Serv. U. S., Hyg. Lab., Bul. 63, 1910, pp. 72, pls. 43, fig. 1).—Eleven species of Dermacentor are considered, 2 being described for the first time.

The sugar-cane insects of Hawaii, D. I. VAN DINE (U. S. Dept. Agr., Bur. Ent. Bul. 93, pp. 54, pls. 4, figs. 5).—In this bulletin the author has brought
together information on the Hawaiian sugar-cane insects. Particular attention is given to the biology of, and remedial measures for, 4 of the more important pests, namely, the sugar-cane leafhopper (Perkinsiella saccharicida), the Hawaiian sugar-cane borer (Rhabdocnemis [Sphenophorus] obscurus), the Hawaiian sugar-cane leaf-roller (Omiodes accepta), and the sugar-cane mealy bug (Pseudococcus caleolaria). Brief mention is made of miscellaneous insects and rats injurious to sugar cane in Hawaii.

The broad-nosed grain weevil (Caulophilus latinasus) (pp. 19-24).—This weevil, first described from Florida in 1881, appears to be permanently established as an enemy of dried cereals and other food materials in the United States, having been recorded or received from Georgia and South Carolina as well as Florida, and from Jamaica, Porto Rico, Mexico, Guatemala, and Madeira.

A bibliographical list of 14 titles is included.

The long-headed flour beetle (Latheticus oryzae) (pp. 25-28).—This beetle was first described in 1850, having been found in rice from Calcutta and elsewhere, including England, and being also known from Arabia, Norway, Italy, and from a London granary in samples from Bussorah, Persia, and Odessa, Russia. Quite recently it has been introduced into this country, having been collected at Houston, New Brannfels, San Antonio, Galveston, Fort Worth, Lyons, Wichita Falls, and Dallas, Tex., and Detroit, Mich. Thus it is established in Texas, and probably in Michigan, and bids fair to become a pest in time.

A bibliographical list of 10 titles is given.

Need of national control of imported nursery stock, C. L. Marlatt (U. S. House of Representatrices, 61 Cong., 3 Sess, Rpt. 1858, pp. 7-16; Jour. Econ. Ent., 4 (1911), No. 1, pp. 107-124).—This paper treats of the plant diseases and insect pests that have been introduced into the United States, of the immense expense attending the efforts of the Federal Government and the States to combat them, and of the history of legislation on the subject.

The effect of certain gases and insecticides upon the activity and respiration of insects, G. D. Shafer (Jour. Econ. Ent., 4 (1911), No. 1, pp. 37-50).—A brief of results obtained in investigations conducted with a view to determining the way in which insects are killed by contact with insecticides.

Some properties that make lime-sulphur wash effective in killing scale insects, G. D. Shafer (Jour. Econ. Ent., 4 (1911), No. 1, pp. 50-53).—This is an abstract of a paper presented at the twenty-third annual meeting of the American Association of Economic Entomologists.

FOODS—HUMAN NUTRITION.

Food and the principles of dietetics, R. Hutchinson (New York, 1911, 3 ed., pp. XX+615, pls. 3, figs. 32).—The author states that the whole volume (E. S. R., 17, p. 1097) has been thoroughly revised and that the chapters dealing with the use of diet in disease have been considerably enlarged. A new chapter has been added on certain dietetic cures and systems.

Wheat studies, E. F. Ladd (North Dakota Sta. Rpt. 1910, pp. 24-31).—The milling and baking tests summarized have been noted from other publications (E. S. R., 24, pp. 67, 262, 263).
The utilization of the whole grain for food purposes, D. Finkler (Jour. Roy. Inst. Pub. Health, 19 (1911), No. 4, pp. 193-199, pls. 2).—In this article the author summarizes data regarding his process for grinding bran in such a way that the cell walls are ruptured and the cell contents made available, and reports experiments establishing the digestibility of breads prepared with the addition of varying quantities of the special bran flour obtained (E. S. R., 23, p. 363). The conclusion reached is that such breads are as well assimilated as ordinary breads and that therefore the bran flour ground by the special wet method is well digested.

Concerning German grains—the baking quality of rye and wheat flour, M. P. Neumann and K. Mois (Ztschr. Gesam. Getreidezw., 2 (1910), Nos. 8, pp. 187-191; 9, pp. 208-215; 10, pp. 231-238).—A large number of varieties of wheat and rye are included in this comparative study, in which the influence of fertilizers is taken into account as well as other factors. In the case of rye flour, the conclusion is reached that the protein content has even less effect on baking quality than in the case of wheat flour. In general, the conclusions have to do with the varieties most satisfactory for local agricultural conditions.

Bacterial leaven of salt-rising bread, H. A. Kohman (Nat. Baker, 14 (1909), No. 164, pp. 39-41).—From his studies the author concluded that the leavening agent in salt-rising bread fermentation is a bacterium and not a yeast.

The fermentation in salt-rising bread is quite different from yeast fermentation. For every pound of carbon dioxide produced by yeast there is something more than a pound of alcohol produced, while the bacterial fermentation in salt-rising bread is nonalcoholic.

He succeeded in isolating the bacterium in pure culture, and states that the organism can be propagated without any difficulty. He also states that he has prepared it for use by growing it in milk and then adding the milk to the sponge and also by making a batter with fermented milk and flour. "This batter when dried can be used as a starter, and then the ordinary method can be followed. A very small quantity of the starter is sufficient to set up a vigorous fermentation."

[Bread making studies]—report of association fellowship student at University of Kansas, H. A. Kohman (Nat. Assoc. Master Bakers [Proc.], 13 (1910), pp. 29-37, fig. 1).—Experimental studies led to the conclusion that the addition to dough of some saccharin material such as sugar and malt extract is justifiable, and that "very often when the yeast works slowly, especially toward the end of the fermentation period, when it is most essential that the bread rises well, it is due to the lack of these."

The activity of several sorts of malt extract was tested and the amount of sugar determined in breads made with the addition of cane sugar, malt extract, and cooked flour, and in bread made without any such additions. Nearly as much sugar was found in the bread made with ½ per cent malt and 3½ per cent cooked flour as in that made with 2½ per cent cane sugar. This the author attributes to the fact that gelatinized starch is a favorable medium for the development of the yeast plant. His experiments led him to conclude that many starch granules of the flour remained intact even after the bread was baked.

"While the use of malt extract in bread making has its advantages, it certainly becomes necessary to exercise more care than when sugar is used." Not more than 1 per cent of malt extract, especially if strong, is needed, too much resulting in a sticky dough of dark color. "The amounts that can be successfully used depend both upon the strength of the flour and the activity of the extract. With a weak flour one must use low diastatic extracts, while with
stronger flours one may use larger quantities or extracts with a greater digestive power."

The effects of the addition of acids, enzymes, and 2 sorts of bacteria isolated from flour were studied with a view to determining their effect when normally present in doughs. "Proteolytic enzymes had a very marked effect upon the gluten when introduced into a dough. They had to be used in very small quantities or the dough would become runny and sticky. As little as one part to 4,000 parts of flour produced a noticeable effect, and when used in larger quantities it was decidedly harmful. While it was not possible to improve bread by adding them, the experiments did show, however, why flours that had germinated and certain malt extracts with a high proteolytic power are not suitable for making bread. Acids, when added to a dough, have a marked 'shortening' effect upon the gluten, and up to a certain strength, depending upon the flour, they shorten the period of fermentation somewhat. In excess, they are decidedly harmful, for they weaken the flour and produce bread which resembles that made with impure yeast."

In no case did the bacteria studied retard the action of the yeast. "In all cases they had a 'shortening' effect upon the gluten, and hence shortened somewhat the period of fermentation. In general, the bread made by the addition of bacteria was smaller in volume and closer grained, approaching more nearly homemade bread."

The studies with salt-rising bread noted above were continued. The author found that with this method of bread making the losses were 0.16 per cent as compared with 1.81 per cent in the case of yeast bread put into pans at once upon mixing the dough, and 5.15 per cent in yeast bread normally fermented. The greater loss in yeast bread is in part due to the longer fermentation period required.

In salt-rising bread, according to the author, no alcohol is produced, and nearly two-thirds of the gas produced is hydrogen. He states that the method of making salt-rising bread with pure cultures of the bacterium isolated has given satisfactory results on a commercial scale.

In connection with an attempt to devise a method of saving stale bread, experiments were made to see whether it could not be used in place of cooked flour in bread making to improve the yeast growth. The bread was ground, cooked with about 5 times its weight of water, cooled to about 131°, and submitted to the action of malt extract. The starch was first liquefied and then converted for the most part into sugar and dextrin, the gluten remaining in small flakes. It was proposed to use the sugar thus formed as part of the liquid in the next day's baking instead of cane sugar or malt extract. The separated gluten when dried, the author considers, may have some value as a diabetic food or for some similar purpose.

[Maize starch product in bread making], A. P. Pfeil (Nat. Baker, 14 (1909), No. 161, pp. 51, 56).—Preliminary experiments are reported on the value of gelatinized starch, in connection with small quantities of malt extract, in bread making to insure vigorous growth of the yeast, which depends in large measure upon an abundance of sugar or sugar-yielding matter.

Analyses of banana flour, J. A. Berthet (Bol. Agr. [Sao Paulo], 12, 1911, No. 2, pp. 127, 128).—Analyses of 2 samples are reported.

Cheestnut flour, G. Leoncini and C. Manetti (Staz. Sper. Agr. Ital., 44 (1911), No. 1, pp. 66-83).—Analyses are reported of 8 samples of chestnut flour, and its nutritive value discussed.

Peculiar spoiling of Brazil nuts, Kühl (Pharm. Zentralhalle, 51 (1910), No. 6, p. 106; abs. in Ztschr. Untersuch. Nahr. u. Genussm., 21 (1911), No. 10, pp. 629, 630).—The spoiled nuts showed the presence of Aspergillus
EXPERIMENT STATION RECORD.

flarus, which the author points out is poisonous. The presence of this fungus
has a possible importance since the nut is so largely used by vegetarians.

Bruxelles [Proc.], 1 (1910), Sect. 3, pp. 121-126).—From a summary of data
the author concludes that the sale of very young veal should be prohibited.
The nutritive value of such veal, he points out, is extremely low. 60 per cent
of the dry matter consisting of extractives and gelatinoids. Moreover, it has
laxative properties, and is handled and marketed under conditions which the
author believes promote disease.

Analyses of sour milk curd, R. Windisch (Kisérlet. Közlem., 14 (1911), No.
2, pp. 167, 168).—The analytical data reported are based on the analysis of a
large number of samples. Such cottage cheese is much used in Hungary sea-
sioned in various ways, and also in the preparation of a number of dishes.

Bruxelles [Proc.], 2 (1910), Sect. 4, pp. 192-194).—Du Santos coffee of good
quality was studied under conditions resembling those which prevail when coffee
is injured by rain or by soaking in sea water, and the composition of the
treated berries compared with that of normal coffee berries. Attempts were
also made to improve and utilize the damaged coffee after roasting it at a
temperature of 250°.

According to the authors, coffee soaked in fresh water undergoes alcoholic
fermentation; then it becomes moldy and changes color, turning green and then
black, the final discoloration being attributable to a zymase (lactase). The loss
of solid substance amounts to 11.1 per cent. If decomposition is arrested
promptly the coffee can be used and is harmless. If the changes are more
pronounced, the decoction has an undistinguishable musty taste and the peculiar
coffee flavor is lost. Coffee soaked in sea water undergoes greater and more
undesirable changes.

Composition of some genuine wine from the Province of Florence, R.
Salvadori and A. Mazzaron (Bol. Min. Agr., Indus. e Com. [Rome], 10 (1911),
Ser. C, No. 5, pp. 43-47).—Fifty-four analyses are reported and discussed.

Aliment., Bruxelles [Proc.], 2 (1910), Sect. 4, pp. 9-12).—It was found in a
study of the acetic acid content and appearance of 20 samples of vinegar, kept
from 7 to 17 months, that, in general, the loss of acid was insignificant and the
change in appearance small. When the acid content was noticeably lowered the
vinaigres lost their clearness, and in some cases were viscous and unattractive.
Such qualities, when found in weak vinegar, the author attributes to spontaneous changes. If, on the other hand, the vinegar is clear, its weak-
ness may be due to dilution with water or to the action of micro-organisms
which have been removed by straining.

9).—Results are reported of an examination of a large number of samples of
tomato catsup collected in different parts of Canada.

Austrian food code (Codex Alimentarius Austriacus. Vienna, Goyt., 1911,
vol. 1, pp. XIV+461).—This important volume contains definitions and specif-
cations for food materials, beverages, and petroleum, together with a summary of
legislative enactments and similar material, and as a whole is the official source
of information regarding the examination and valuation of food and certain
other products in Austria. A large number of experts have participated in the
preparation of material for the codex. The preface is by F. W. Dafert, who is
the head of the commission having the work in charge, and there is also an
historical introduction explaining the development and extent of the Austrian
work with respect to valuation and the suppression of adulteration and sophisti-
cation of foods and other materials. The present codex is the outgrowth and completion of an enterprise begun under different auspices a number of years ago.

Analyses and inspection work at the agricultural-chemical, experimental, and food laboratory at Vorariberg in Bregenz in 1910, J. M. Krasser (Ztschr. Landr. Versuchsw. Österr., 14 (1911), No. 4, pp. 582-591).—Information is given regarding the character and extent of the analytical and inspection work carried on. Analyses of commercial soup flavorings are reported and information given regarding the food inspection work, regulations governing the sanitary handling and marketing of foodstuffs, and the inspection of fertilizers.

Food inspection decision (U. S. Dept. Agr., Food Insp. Decision 138, p. 1).—This decision, which has to do with saccharin in food, is a modification of Food Inspection Decision No. 135 (E. S. R., 25, p. 368).

Notices of judgment (U. S. Dept. Agr., Notices of Judgment 895, pp. 3; 896-937, p. 1 each; 936-956, p. 2 each; 968-987, p. 1 each; 987-997, pp. 2 each).—The notices of judgment have to do with the misbranding of coffee, pork and beans, drug products, Marschino cherries, lemon flavor, Harris's lithia water, evaporated apples, flower, preserves, "matzos," "pineapple" oranges, lemon extract, Buckhead lithia water, olives, a food product ("Crown glossine"), "figprune cereal," and headache tablets; the adulteration of ice cream cones, tomato pulp, Jamaica ginger compound, tomato catsup, frozen eggs, tomato ketchup, shelled peanuts, evaporated peaches, prunes, coffee, confectioners' brown glaze, and eggs; the adulteration and misbranding of a drug product, tomato catsup, olive oil, vinegar, blackberry cordial, maple syrup, spirits turpentine, vanilla flavor, "Yani-Kola compound syrup." Jamaica ginger and flavoring extracts (peppermint and wintergreen), flavoring extracts (vanilla, lemon, and strawberry), evaporated apples, coffee, "salad oil," "true eggs substitute," tomato paste, vanilla extract, and cider vinegar; the alleged misbranding of "flavor of lemon and citral;" the misbranding and alleged adulteration of vinegar; the adulteration and alleged misbranding of evaporated apples; and the alleged adulteration and misbranding of olive oil.

The influences on the digestive processes of different beverages taken during meals, Ibn (2. Cong. Internat. Hyg. Aliment., Bruxelles [Proc.], 1 (1916), Sect. 2, pp. 23-29).—From investigations carried on in the author's laboratory, he concludes that except in cases of abnormal digestion or of toxic beverages the influence of beverages on digestion is ordinarily much exaggerated. Liquids taken in ordinary amounts may lessen the acidity of the gastric contents for a short time, but the effect is too small to be important. Tea and coffee the author regards as stimulants to the secretion of digestive juices. Milk is separated into water and curd as soon as it reaches the stomach, and its liquid therefore affects digestion no more than does water. In most beverages of acid and alkaline properties the latter are so feeble that they intensify or neutralize the acidity of the gastric contents to only a very slight degree. In the opinion of the author the question of whether beverages are appetizing is more important to persons in health than their chemical nature.

The biological rôle of potassium, E. Biernacki (Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, n. ser., 6 (1911), No. 10, pp. 401-407).—The data reported
have to do with the effect of diet on the excretion of potassium. According to the author, the excretion is greater on a diet rich in protein and poor in carbohydrates than on one in which these conditions are reversed.

The relation between potassium excretion and sodium is also considered. See also a previous note (E. S. R., 25, p. 67).

A critical study of the process of acid excretion, L. J. Henderson (Jour. Biol. Chem., 9 (1911), No. 5, pp. 403-424, dgrns. 3).—As is the case with temperature and osmotic pressure, normal neutrality or alkalinity, the author concludes, is adjusted by a mechanism within the body, but is maintained permanently by exchanges with the environment.

"The acid end products of metabolism, without appreciably changing the actual alkaline reaction constantly take up alkali from blood and protoplasm. In this manner there is a tendency to disturb the normal protective equilibrium between bases and acids. This tendency is held in check by the kidney, which in the process of urine formation reverses the reaction of neutralization of acid and restores to the blood that alkali which has served as a carrier of acid.

"The process may be measured both quantitatively and in respect to its efficiency. The quantity of acid excreted is measured by the amount of alkali which must be added to urine in order to obtain the reaction of blood plus the amount of urininary ammonia."

A method for carrying out such measurements is described.

According to the author's investigations "the preservation of the normal alkalinity of the body is due, in important measure, to but two independent factors, excretion of ammonia and excretion of phosphates. The elaboration of ammonia and the presence of phosphoric acid as an end product of metabolism make possible the excretion of acid; regulation of ammonia production and of the ratio of the acid to the alkaline phosphates of urine are the means of regulating the acid excretion."

The pressor bases of the urine—the effect of age, diet, and high blood pressure on their excretion, W. Bain (Lancet [London], 1911, I, No. 21, pp. 1409-1411, figs. 3).—Pressor bases—that is, substances which raise the arterial blood pressure of animals when injected intravenously—are absent from the urine of children from 10 to 12 years of age and apparently begin to be excreted at about the age of 14.

"A vegetable diet considerably reduces the amount formed. Eggs and fish reduce the quantity to some extent, but if chicken is taken the amount is but little less than one obtains on an ordinary mixed diet containing butcher's meat.

"The bases are either absent or considerably diminished in cases of high blood pressure. Doubtless the diminution in some cases is partially attributable to low dietary, but in most of the cases recorded in this paper the only possible explanation is that the bases are retained in the system and produce the rise in pressure.

"In gouty patients with normal blood pressure the pressor bases are excreted in normal amounts."

The energy value of food materials and dietary standards, H. Kettlitz 2. Cong. Internat. Hyg. Aliment., Bruxelles [Proc.], 1 (1910), Sect. I, pp. 23-33).—From a summary of data the author concludes that the conflicting results obtained by the various investigators indicate clearly that nutritive requirements vary with individuals and with the same individual under differ-
ent conditions, and that the prescription of a diet, like the practice of medicine, is therefore an art rather than an exact science.

Diet of the white man in the Congo, Dryepondt (2. Cong. Internat. Hyy. Aliment., Bruxelles [Proc.], 1 (1910), Sect. 2, pp. 66-78).—Many questions which concern the selection and preparation of food, the character of the diet which is desirable, etc., are discussed. The author believes that in tropical regions generous amounts of meat combined with a moderate amount of vegetables should be used, since animal foods require less expenditure of energy for their digestion and assimilation, while, on the other hand, vegetable foods increase a tendency to diarrhea and dysentery. The natives, he states, live on a vegetable diet in times of peace, but use animal foods when engaged in warfare. Similarly, when they are hired to perform fairly severe work for Europeans, it has been found necessary to give them meat. Much information is summarized regarding the character and food qualities of native food materials.

A campaign ration, J. B. E. Haefele (2. Cong. Internat. Hyy. Aliment., Bruxelles [Proc.], 2 (1910), Sect. 7, pp. 33-41).—French army rations are discussed, and suggestions made regarding the use of less bulky rations when on the march or in the field.

Diet in Belgian prisons, H. Vandeputte (2. Cong. Internat. Hyy. Aliment., Bruxelles [Proc.], 1 (1910), Sect. 2, pp. 37, 38).—The amount of nitrogen and carbon supplied in central and secondary prisons in Belgium is calculated. Though doubtless adequate, the diets are not regarded as satisfactory, owing to their extreme simplicity and monotony. Some method for introducing variety is advocated, such as possibly the purchase of additional materials at the prison canteen.

Dietaries in Belgian prisons, F. Dauwe (2. Cong. Internat. Hyy. Aliment., Bruxelles [Proc.], 1 (1910), Sect. 2, pp. 49-65).—The winter and summer diet of the central prisoners, according to the author’s summary, supply, in round numbers, 138 and 129 gm. protein per day, respectively, with an energy value of 3,390 and 3,320 calories. Similar values for the winter and summer diet of the secondary prisoners are 120 and 111 gm. protein and 3,225 and 3,131 calories. These figures represent food as purchased. Attention is drawn to the monotonous character of the diet, and some suggestions are made for improvement.

The diet of prisoners, Delmarcel (2. Cong. Internat. Hyy. Aliment., Bruxelles [Proc.], 1 (1910), Sect. 2, pp. 39-48).—According to the author’s summary, the diet in Belgian central and secondary prisons supplies about 100 gm. protein and from 2,800 to 2,900 calories per day.

The proportion of wages spent to cover the expenditure of the body during the performance of a definite amount of mechanical work, A. M. Imbert (2. Cong. Internat. Hyy. Aliment., Bruxelles [Proc.], 1 (1910), Sect. 1, pp. 173, 174).—The author concludes that about 1/15 of the daily income (80 cts. in round numbers) was spent for the portion of the food which provided the energy (500 calories) expended in mechanical work performed by the subject under investigation.

The possibility of increasing the working power of muscles by training, E. Palmén (Skand. Arch. Physiol., 24 (1910), No. 2-4, pp. 163-186, dgrms. 3).—The results of an extended study showing the beneficial effects of training are reported, in which the work consisted in raising a weight.

The effect of different variables upon fatigue, E. Palmén (Skand. Arch. Physiol., 24 (1910), No. 2-4, pp. 197-225, dgrms. 5).—The investigations have to do with the work noted above.
The energy problem from the standpoint of muscular work and intellectual work. H. RENAUD (2. Cong. Internat. Hyg. Aliment., Bruxelles [Proc.], 1 (1910), Sect. 1, pp. 11-14).—According to the author's summary, the same general laws which govern muscular work hold also for mental work.

The brain, he concludes, is subject to osmosis, as are the other organs of the body. As the muscle cells when they become active utilize some form of carbohydrate, so the cerebral cells utilize a special substance, chromatín. Morphological changes corresponding to those in the glandular cells which produce external secretions also take place in the cortical cells according as the latter are in a state of psychic activity or repose. Psychic activity, like muscular activity, occasions an increased flow of blood through the organ and an increase in waste products, as is shown by the highly toxic character of the urine in subjects performing severe intellectual work. But whereas in the case of muscular activity the chemical reactions and heat liberation can be localized and measured in the muscle itself, this has not yet been done in the case of intellectual activity. In the latter not one set of cells, but probably the entire neuro-muscular system, is called into play. In short, while it has been demonstrated that the law of the conservation of energy holds in mental work, it has up to the present time been impossible to measure the exchanges which accompany it.

Friction in the bomb calorimeter, H. A. ROESLER (Amer. Chem. Jour., 44 (1910), No. 1, pp. 80-84; abs. in Chem. News, 103 (1911), No. 2667, pp. 2, 3).—A method for determining the heating effect due to the friction of the stirrer in bomb calorimetry work was evolved, and the results of a number of determinations reported. The magnitude of the rate of rise in temperature, due to such friction, does not affect the accuracy of the heat determinations, according to the author, provided it is uniform throughout the time of the determination.

ANIMAL PRODUCTION.

Breeding farm animals, F. R. MARSHALL (Chicago, 1911, pp. 287, figs. 49).—As stated in the preface, "the main object of this book is to direct attention away from profitless speculations that have necessarily characterized some earlier books, and to stimulate interest in the more tangible, the physical basis of heredity. . . . It has been the aim to limit discussion to points upon which scientific opinion is quite well agreed, though this has not been altogether possible."

In the chapters on "germ cells," "the offspring during gestation," and "Mendel's law" will be found such information as the author has gleaned from the biological field that is of value to the practical breeder. The author shows that a scientific study of the physical aspects of heredity lead to conclusions that are in accord with the teachings of the men who have produced the best types of horses, cattle, sheep, and swine. Among the chapters devoted to the practical side of breeding are the following: Pedigrees of breeding animals, foundation and management of a breeding business, and breeding associations.

On the interrelations of genetic factors, W. BATESON and R. C. PENNETT (Proc. Roy. Soc. [London], Ser. B, 83 (1911), No. 568, pp. 3-8).—Results obtained with plants examined in the light of the presence and absence hypothesis showed two distinct conditions, first, a system of partial coupling under which two factors are generally associated, and a system of complete repul-
sion (spurious allelomorphism). Further work showed that there had been a repulsion in one case between the same two factors which had been coupled in another case. The authors come to the conclusion that if \( A, a, \) and \( B, b \) are two allelomorphic pairs subject to coupling and repulsion the factors \( A \) and \( B \) repel each other in the gametogenesis of the double heterozygote resulting from the union \( Ab \times ab \), but will be coupled in the gametogenesis of the double heterozygote resulting from the union \( AB \times ab \). The \( F_1 \) heterozygote is ostensibly identical in the two cases, but its offspring reveals the distinction. The possible significance of coupling and repulsion for breeding operations is discussed.

Under a given system in which a pair of factors are coupled it is possible to produce repulsion by breeding together the rarer terms of the coupled series, namely, \( Ab \) and \( aB \), but the authors see no way to construct a coupling system for the repelling system in the absence of a fresh variation. "This consideration has an obvious application to those cases in which sex operates as a repelling factor. In the fowl, the canary, and *Abraxas grossulariata* femaleness thus acts as a repelling factor against various elements determining pigmentation, and our experience of the plants leads us to suppose that if the factors involved could be built up in the right combinations femaleness might be coupled with the factors it now repels."

"Extraordinary consequences, both to the distribution of the sexes, to the distribution of factors between them, and perhaps to the causation of fertility, must be anticipated if this condition could be fulfilled. There may be an indirect way of actually accomplishing these results. For, seeing that sex in the fowl acts as a repeller of at least three other factors, when birds are built up so as to be heterozygous for several of these, some of them may be found able to take precedence of the others in such a way as to annul the present repulsions, with subsequent coupling as a consequence."

Double mating of silkworm moths, W. E. Castle (*Science, n. ser.*, 34 (1911), No. 862, pp. 15-21).—Comments on the article noted above are given, the view being expressed that double mating has produced nothing at variance with the results of single mating, but that the work under discussion demonstrates variance in dominance in common with results obtained by Couatgne and Toyama.

Economic importance of live-stock production, H. W. Mumford (*Amer. Breeders Mag.*, 2 (1911), No. 1, pp. 46-52, figs. 3).—This contains statistics on the world's supply of live stock, and the importance of increasing the live-stock production of this country is pointed out.

On the botanical and chemical composition of different varieties of hay, R. Tacke (*Fühling's Landw. Ztg.*, 59 (1910), No. 11, pp. 361-374; *abs. in Zentral. Agr. Chem.*, 40 (1911), No. 3, pp. 192-197).—Chemical analyses are reported of samples of hay which were gathered from different places, the chief object being to compare marsh hay with that grown on the moors. The species of grasses composing the principal part of each sample of hay are enumerated.

Special feeding stuff analyses, 1911, R. E. Rose and E. P. Greene (*Fla. Quart. Bull., Dept. Agr.*, 21 (1911), No. 3, pp. 192-169).—Analyses are reported
of cottonseed meal, bran, middlings, ship stuff, rice flour, hominy feed, dried beet pulp, and mixed feeds.

Stock foods and feeding stuffs, E. F. Ladd (North Dakota Sta. Rpt. 1909, pp. 30, 31).—Analyses are reported of wheat bran, shorts, middlings, mixed feeds, and stock foods.

Feeding stuffs, E. F. Ladd (North Dakota Sta. Rpt. 1910, pp. 40, 41).—Analyses are reported of middlings, corn and oats, ground oil meal, flax bran, molasses feed, and proprietary mixed feeds.

On the use of corn cobs for feeding animals, L. Danesi and F. Scurri (Staz. Sper. Agr. Ital., 43 (1910), No. 3, pp. 273-282; abs. in Zentbl. Agr. Chem., 40 (1911), No. 5, pp. 355, 359).—Analyses are reported on the nutritive value of corn cobs from different varieties of corn, and their value for feeding stock is discussed.

Notices of judgment (U. S. Dept. Agr., Notices of Judgment 902, 913, p. 1 each; 923, pp. 2).—These relate to the adulteration of alfalfa hay and stock feeds.

Observations on ruminations, E. Belz (Physiologische und Klinische Beobachtungen über die Ruminations. Inaug. Diss., Univ. Giessen, 1910, pp. 92; rev. in Zentbl. Biochem. u. Biophys., 10 (1910), No. 9-10, pp. 453, 454).—The average number of movements of the jaw to masticate 1 bolus was as follows: Grown cattle, 49; calves, 60; sheep, 78; and goats, 60. The number of seconds the bolus remained in the mouth was for mature cattle 53, calves 55, sheep 61, and goats 70. Ruminations began from $\frac{3}{4}$ to 1$\frac{1}{4}$ hours after eating. In all ruminants there were from 4 to 6 masticating periods, lasting from 23 to 35 minutes.

The significance of the mechanical part of the energy of digestion of cattle, K. Dahm (Biochem. Ztschr., 28 (1910), No. 5-6, pp. 456-503; abs. in Zentbl. Physiol., 25 (1911), No. 2, p. 86).—To compare a ration rich in fiber with an easily digested ration a young bull was given a daily ration of 5 kg. of hay and 1 kg. of barley for 10 days. In the second period of the same length the ration consisted of 1.5 kg. of hay and 2.5 kg. of barley. This contained 1,080 gm. less of raw fiber than the former ration, and required 549 calories less energy. The energy required for chewing and for ruminating 1 kg. of hay was determined to be 52.3 and 41.9 calories, respectively. Eight per cent more energy was required when standing than when lying down.

On substituting a foreign fat for milk fat in feeding skim milk to calves, C. Besana (Staz. Sper. Agr. Ital., 43 (1910), No. 1, pp. 86-90; abs. in Zentbl. Agr. Chem., 40 (1911), No. 7, pp. 501, 502).—Margarin and skim milk were gradually substituted for whole milk in feeding 4 calves, which made an average daily gain of 0.717, 1.23, 0.897, and 0.923 kg., respectively.

Breeding from ewes at an early age, J. Mackintosh (Jour. Southeast. Agr. Col. Wye, 1910, No. 19, pp. 25-29).—A later report of work previously noted (E. S. R. 25, p. 273). During the second year the difference in weight between the 2 lots of ewes was diminished because the earlier bred ewes lost much less in live weight than did the lot of ewes mated at 20 months of age.
The caracul breed of sheep, C. C. Young (Amer. Breeders Mag., 2 (1911), No. 1, pp. 34-46, figs. 9).—This is a discussion of the characteristics of the different types of Arabi or caracul breed of sheep, and on the characters of the fleece obtained from crosses with Arabi breeds, which the author thinks are superior to the imported Persian lamb skins now sold in the United States. Crosses with long wools, particularly Lincolns, have so far produced the best fleeces.

[The supply of mutton and wool to Great Britain from outside sources] (Mark Lane Express, 105 (1911), No. 4161, pp. 875, 877, 879).—An extract of a paper read before the Twelfth International Conference of Sheep Breeders, Norwich, England, June, 1911, in which are forecasted the probable sources of the world’s future supplies of mutton and wool.

Sheep industry of New Zealand, H. D. Baker (Daily Cons. and Trade Rpts. [U. S.], 14 (1911), No. 189, pp. 689-695).—A report on the growth of the present condition of the sheep industry in New Zealand.

Growing hogs in Nebraska, W. P. Snyder (Nebraska Sta. Bul. 121, pp. 49, figs. 5).—This bulletin reports the results of several years' work on (1) the cost of the average pig when it has reached the weight of 50 lbs., (2) the cost of keeping brood sows, and (3) the cost of growing pigs on alfalfa pasture and grain.

Twenty-four old sows, pastured during the summer on alfalfa with no grain, were fed a light ration of corn and alfalfa hay until farrowing time, at a cost of $5.19 for grain and $1.50 for alfalfa hay. The cost of feed from farrowing time until the pigs weighed 50 lbs. was $11.89, and with pasturage at $1.50 the total cost per sow was $20.08. The sows made an average gain of 56 lbs., which is credited at $3.30, making the cost per pig at the above age $2.79.

Young sows weighing about 70 lbs. each, pastured on alfalfa supplemented with a grain mixture of corn and wheat, made an average daily gain per head of 0.57 lb. It required 333 lbs. of grain, at a cost of $3.34, to produce 100 lbs. of gain. They were then put on a scant rye pasture and fed a mixture of corn, barley, and chopped alfalfa until farrowing time. On this feed they gained 0.88 lb. per head daily, requiring 455 lbs. of grain and 153 lbs. of alfalfa, at a cost of $4.56, per 100 lbs. of gain. Charging $1.50 for pasture, the total cost per sow until the pigs weighed 50 lbs. was $22.54. The sows made an average gain of 168 lbs., which is credited at $9.91, making the net cost $2.34 per 50-lb. pig.

In a similar experiment with 20 old sows in which the supplementing feed consisted of corn, wheat, emmer, and alfalfa meal, to which was added a little oil meal after farrowing, the cost per pig at 50 lbs. weight was $1.70.

Twenty-five young sows on alfalfa pasture supplemented with corn and wheat made a daily gain of 0.8 lb. each, at a cost of $3.59 per 100 lbs. gain for the grain. They were then put on a small rye pasture and fed a mixture of corn and barley, and later on corn and wheat with chopped alfalfa until farrowing time. On this ration they gained 0.95 lb. each per day, consuming 430 lbs. of grain and 138 lbs. of alfalfa per 100 lbs. of gain. The pigs from these sows at 50 lbs. of weight cost $1.95 each.

In an experiment with 7 sows with fall litters the feed consisted of alfalfa pasture alone supplemented with a small amount of grain before farrowing. The grain feed after farrowing consisted of corn, wheat, and barley. The cost per pig at 50 lbs. weight in this test was $1.88. "The average results of the 5 preceding lots of hogs indicate that the cost of the 50-lb. pig was $2.13, or at the rate of $4.26 per 100 lbs. This does not include cost of labor or equipment or interest on investment."
In a series of experiments to test the cost of growing pigs on alfalfa pasture and grain, part of which has already been reported (E. S. R., 19, p. 266). 169 pigs in 5 lots, weighing from 57 to 71 lbs. each, were fed from 63 to 112 days. The grain rations consisted of various mixtures of corn, barley, and wheat, and corn alone. The pigs made an average daily gain per head of 0.8 lb., and it required 308 lbs. of grain, at a cost of $2.50, per 100 lbs. of gain. Charging pasture at from 0.3 to 0.4 ct. per head daily, the average cost per 100 lbs. gain for the 5 lots was $3.25.

In another test 18 pigs, averaging 65.4 lbs. each, were fed in 6 lots as above, except that rye was used in some of the grain mixtures. They made an average daily gain per head of 0.67 lb. and required 370 lbs. of grain, at a cost of $3.25, per 100 lbs. gain. Including pasture, the total cost per 100 lbs. gain in this test was $3.73.

In a test in which 113 50-lb. pigs were pastured on alfalfa and fed a full ration of soaked corn the daily gain per head was 0.72 lb. It required 270 lbs. grain, at a cost of $2.27, per 100 lbs. gain, and including pasture, the cost per 100 lbs. gain was $2.48. In a similar test with 97 pigs the gain was 0.51 lb., and it required 303.4 lbs. grain, at a cost of $2.55, or including pasture $2.92, per 100 lbs. gain.

The 210 pigs last mentioned were subsequently divided into 6 lots and were fed corn on alfalfa pasture, except 1 lot, which was fed mixed grain and tankage. The average daily gains per head averaged from 0.9 to 0.98 lb. at a cost, including pasturage of from $2.54 to $4.96 per 100 lbs. gain. “A summary of these 5 years, where 792 pigs were fed various amounts of corn and other grains, indicates that the average cost of the grain and pasture for 100 lbs. of gain was $3.30.”

The author states that in these experiments wheat and barley always increased the cost. In figuring the above cost data the following prices were used: Hogs 5.9 cts. per pound; corn 47 cts., wheat 70 cts., barley 49 cts., rye 56 cts. per bushel; oil meal $30, tankage $40, alfalfa meal $15, chopped alfalfa $10, and alfalfa hay $8 per ton.

Experiments showed that rations for horses could be cheapened by substituting dried yeast and dried potatoes for about one-half of the grain ration. Feeding experiments with swine and white rats, and metabolism experiments with rats and sheep are also reported.

Draft dogs, G. Lavielle (Bul. Mens. Soc. Cent. Agr., Hort. et Acclim. Nice, 50 (1910), No. 10, pp. 554-559; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Int. and Plant Diseases, 1910, No. 2, p. 313).—A historical and statistical account of the dog as a draft animal. At the present time about 150,000 are used for that purpose in Belgium, 10,000 of which are in Brussels and its suburbs. The value of the labor of the dogs per head and day is estimated at 50 centimes (10 cents). An average mastiff can draw a load of from 100 to 150 kg. for a distance of 12 kilometers in an hour without fatigue.

Protein concentrates for winter chickens, B. L. Hartwell and W. F. Kirkpatrick (Rhode Island Sta. Bul. 145, pp. 3-40).—This bulletin reports experiments supplementary to those previously reported (E. S. R., 20, p. 470).

To compare the effect of certain concentrates when fed to winter-hatched chicks, 7 lots, each of 35 White Wyandottes 2 weeks old, were fed a basal ration consisting of corn meal, cracked corn, mixed feed, and alfalfa, supplemented with linseed meal, gluten feed, granulated milk, or animal meal, sufficient in each case to supply an equal amount of protein. Two lots each were fed the
linseed meal, gluten feed, and granulated milk rations. The phosphorus content of the ration of one each of these lots was equalized with that of the animal meal ration by the addition of bone ash, and as this caused an excess of calcium in the granulated milk ration ground limestone was added to all the other rations. The authors state that this experiment emphasizes the necessity of adding ash constituents to rations composed entirely of vegetable products, and that unless this is done development seems almost impossible with such rations. Even the ration containing granulated milk was benefited by the addition of bone ash. "Within 4 weeks the bones of the legs and breasts of the chicks which were fed the rations containing linseed meal and gluten feed, without ash, had begun to be crooked. Even with the ash constituents added these 2 concentrates were unsatisfactory."

To compare the effect of the addition of bone ash and different amounts of ground limestone to the ration 3 lots each of 14 two-weeks old Cornish Game-White Wyandotte chicks were fed the same basal ration as in the previous experiment, supplemented with cottonseed meal on an equal protein basis with the animal meal ration above. Lot 1 received no added ash constituents, lot 2 enough bone ash and ground limestone to supply phosphorus and calcium equal to the animal meal ration in the previous experiment, and the ration of lot 3 differed from that of lot 2 only in having 3 times as much limestone. The experiment was begun October 26, 1907, and by December 2 all the chicks in lot 1 had died. The chicks in lot 2 began to show signs of leg weakness December 20, and 3 afterwards died. None of lot 3 died. The experiment was concluded February 3, 1908, at which time lot 2 weighed 10.29 lbs. and lot 3 13.91 lbs. per 10 chicks.

The concentrates mentioned above and beef scrap were compared in an experiment in which the protein content of each ration was the same but the basal ration so varied that the nutritive ratio was about 1:3, except that the nutritive ratio of the linseed meal ration was lowered to 1:4 on account of stickiness of the mash, and a lot was fed a ration of beef scrap, nutritive ratio 1:4, for comparison. In addition mangel-wurzels amounting to about 30 per cent of the weight of other foods were allowed. The chicks were Rhode Island Reds, about 3 weeks old, 29 being in each lot. The live weight respectively per 10 chicks for the various lots, after 49 days, were as follows: On linseed meal 5.97, cottonseed meal 8.57, beef scrap (1:4) 7.57, beef scrap (1:3) 9.51, animal meal 6.13, gluten feed 6.89, and granulated milk 9.7 lbs.

Bone ash and floats were compared as sources of calcium phosphate. The only difference in condition of the bones that could be detected in the experiment was that the legs of the lot fed floats were slightly more crooked than those of the other lot.

No advantage was derived by the addition of sugar to a ration for finishing broilers fed a basal ration of corn meal, wheat bran, beef scrap, and whole milk.

Different concentrates with limestone grit and a constant amount of bone ash were fed to 7 lots, each consisting of 32 White Plymouth Rock chicks 3½ weeks old and fed a basal ration of corn meal, wheat bran, cracked wheat and corn, and bone ash, supplemented with granulated milk, milk albumin (71.1 per cent protein), cottonseed meal, gluten meal, animal meal, or beef scrap. As in previous experiments, the same amount of protein was supplied in the different concentrates, and the amounts of corn meal and wheat bran were so varied as to secure a nutritive ratio of 1:3, except that one lot was given a smaller amount of milk albumin, making the nutritive ratio 1:4. Beets served as green food. During the course of the experiment certain changes and additions in the basal rations widened the nutritive ratio of all the rations about three-fourths of a unit. The weight per 10 chicks at the end of 70 days was as
follows: Granulated milk lot 8.87, milk albumin (narrower ratio) 13.38, milk albumin (wider ratio) 13.69, cottonseed meal 8.64, gluten meal 7.26, animal meal 10.07, and beef scrap 10.32 lbs.

To compare beef scrap (in both large and small amounts), cottonseed meal, and gluten meal, 4 lots of 21 Rhode Island Reds 4 weeks old were fed from March 17 to May 19. The basal ration consisted of corn meal, wheat bran, cracked corn, and was so varied that, with the same amount of protein furnished by each concentrate, the nutritive ratio was about 1:3 in each case. Ground bone, grit, charcoal, wood ashes, and rock salt were supplied ad libitum, and a recorded amount of beets was fed daily. The beef scrap (lesser amount) lot weighed 11.81 lbs. per 10 chicks, the lot fed beef scrap (larger amount) 12.52 lbs., that fed cottonseed meal 8.09 lbs., and that fed gluten meal 8.17 lbs.

The bulletin concludes with a digest of data in reference to the concentrates used, in which their comparative merits are judged principally with reference to the rapidity of growth, regardless of the amount of food consumed. Further experiments with cottonseed meal are being made.

Is the Ancona a mottled Leghorn or a distinct breed? F. L. Platt, R. W. van Hoesen and F. L. Sewell (Rel. Poultry Jour., 18 (1911), No. 6, pp. 773, 822-824, fig. 1).—A description of the characteristics and early history of this little-known breed of fowls.

The preservation of eggs. R. Berger (Jour. Indus. and Engin. Chem., 3 (1911), No. 7, pp. 493-495; Reprint, pp. 4; Pure Products, 7 (1911), No. 8, pp. 423-425).—The author tested a number of colloids and crystalloids, some of which were absorbed by the shell and some were not.

All of the absorbed substances gave an alkaline reaction. Caustic soda solution readily penetrated the eggs, causing the albumin to coagulate in a few days, and many eggs when immersed in a 5 per cent solution cracked within the first 24 hours. A solution of 1 volume commercial silicate of soda, 40° Baumé, and 15 or 20 volumes of water, closed the pores of the shell within 3 to 7 days, and limewater was fully as effective in this respect. Sodium aluminate solution, 1:15, required from 2 to 3 weeks, and castile soap, 1:20, about a month. Other solutions which closed the pores were those of bicarbonate, di-, and especially trisodium phosphate. A 3 per cent solution of barium hydrate acted much slower than limewater containing about 0.14 per cent hydrate of lime. The concentration was found of great influence. For instance, with silicate of soda, 1:120, none of the eggs would crack within a period of 15 days.

The author also experimented with eggs in crystallized silicate of soda, or "alkasil," Na₂O·SiO₂·H₂O, and 4 grades of commercial silicate of soda. No great difference was found in the pore-sealing action, but the weights of the eggs increased in the crystallized silicate of soda, the increase ranging from 0.0 per cent in 1 week to 2 per cent in 5 weeks. A similar increase in weight of eggs resulted when the latter were immersed in commercial silicate of soda in which the SiO₂ percentage had been decreased by the addition of caustic soda or lime to such an extent that only 3 molecules or less of SiO₂ were in combination with 2 molecules of Na₂O in the solution. While the weights of many eggs preserved in silicate of soda remained constant within very close limits, there were considerable variations in eggs preserved in limewater and especially in silicate of soda with a low percentage of SiO₂.

To test the permeability of the shells of preserved eggs, a number were kept in the open air for several weeks, and it was found that they would still crack when boiled. After 6 months in the open air their average loss in weight was only 6 per cent, against nearly 20 per cent on unpreserved eggs.

Directions for preserving eggs in silicate of soda are given,
DAIRY FARMING—DAIRYING.

Second report of grade dairy herd, A. C. Anderson (Michigan Sta. Bul. 264, pp. 75–89).—This bulletin is a report of the milk and butter production, food consumption, and profits for 3 years of the grade dairy herd used in an experiment in herd improvement, and in part has already been reported (E. S. R., 18, p. 172).

The average of 36 records of 21 cows, some of the cows having records for 1, some for 2, and some for 3 years, was 6,228 lbs. of milk and 286.6 lbs. of butter. The average profit per cow over cost of feed was $33.00. The best cow was kept at a profit of $40.57 and the poorest at a profit of only $3.21. The feeding and management of the herd are reported in detail, and comments on a few of the individual cows are included.

The returns from 59 farms showed that the average cost of feed per gallon of milk was 6.58d. (13.16 cts.), with a range from 3.83 to 10.54d. The cost of feed per cow per day ranged from 7.8 to 24.1d., with an average of 14.88d.

A study of the methods of feeding showed that where large amounts of hay or roots were fed the cost of production was increased.

Progress in selection as shown by advanced register records, M. W. Harper (Amer. Breeders Mag., 2 (1911), No. 1, pp. 10–19).—Data from advanced registry of the Jersey and Holstein breeds are presented in tabular form to show that the average and maximum milk production of these breeds as a whole have been raised by discarding the low producers as breeders.

Dairy farm management in the Ozarks, L. A. Allen (Missouri Bd. Agr. Mo. Bul., 9 (1911), No. 6, pp. 29, figs. 10).—A study of methods practiced on dairy farms in the Ozarks. Data gathered from other sources are presented, which suggest some important changes in the present system for dairy farming in that region.

Some interesting statistics of creamery work in several important States for the year 1910 (N. Y. Produce Rev. and Amer. Cream., 32 (1911), No. 12, p. 444).—This contains data on the amount of butter made, cost of making butter, price paid for butter fat, etc., compiled by the Dairy Division of this Department from reports of creameries in Minnesota, Wisconsin, Iowa, Michigan, and South Dakota.

Cooperative dairies (Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Intern., 2 (1911), No. 5, pp. 5–30).—This is a statistical account of the cooperative dairies in Germany. In 1910 there were 3,364, of which 2,155 belonged to the National Federation of German Cooperative Societies. The average quantity of milk each society supplied per day in 1908 was 3,671 kg., an increase of nearly 50 per cent since 1892.

The development of cooperative dairies (Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Intern., 2 (1911), No. 5, pp. 115–123).—A general and statistical article pertaining to the rapid growth of cooperative dairying in Russia, particularly in Siberia.

Municipal milk supply in Germany, A. Gradenwitz (Sci. Amer. Sup., 72 (1911), No. 1854, pp. 40–42, figs. 5).—A description of the centralized plant for handling the milk supply of the City of Dresden, where the problem of the handling of milk under sanitary conditions has been solved by placing the receiving station for milk under municipal control.

The Copenhagen Milk Supply Company, A. M. Trotter (Jour. Meat and Milk Hyg., 1 (1911), Nos. 6, pp. 314–322, fig. 1; 7, pp. 359–367, figs. 2).—This is
an account of the origin, methods, and results accomplished by this pioneer institution for obtaining a sanitary and cheaper milk supply.

The precipitation of iron from the dairy water supply (Molk. Ztg. [Hildesheim], 25 (1911), No. 58, pp. 1095, 1096).—A method is described for removing iron from water when present in such quantities as to be detrimental to dairy products.

On the mode of production of lactose in the mammary gland, D. N. Paton and E. P. Cathcart (Jour. Physiol., 42 (1911), No. 2, pp. 179-188, charts 2).—The injection of phloridzin into a goat reduced the amount of milk secreted. The amount of lactose in the milk was also reduced, the lowest output being reached either on the day that the largest output of sugar occurred in the urine or just after this. These experiments are taken to indicate that the glucose of the blood is used by the mammary gland in the formation of lactose. The question is still unsettled regarding the source of the galactose.

Some physical and chemical properties of woman's milk, Jeannette Polenaar and H. Filippo (Ztschr. Expft. Path. u. Ther., 9 (1911), No. 1, pp. 138-145; abs. in Chem. Zentbl., 1911, II, No. 1, p. 39).—The results represent a 14-day test with woman's milk, in which the viscosity, electrical conductivity, and freezing point were determined.

Between normal and abnormal cases (such as low yield of milk, albuminuria, or acute or chronic diseases) no difference in viscosity could be noted, as in all instances a regular progressive diminution of the viscosity took place. The electrical conductivity was increased in most instances in the abnormal samples, being greatest in the case of diminished milk secretion, and least in the case of albuminuria. In the normal samples a periodic decrease in the electrical conductivity took place during the first week of lactation.

Contributions to the significance of lime and phosphoric acid in the animal body.—I, Influence upon milk secretion of rations deficient in lime and phosphoric acid, G. Fingerling (Landw. Vers. Stat., 75 (1911), No. 1-2, pp. 1-52).—Digestion experiments were made with 2 milk goats which were fed rations composed of hay and sesame cake, which are relatively rich in phosphoric acid and lime, as contrasted with a ration of straw, dried-beet chips, gluten, and peanut oil, feeds which are deficient in the lime-phosphorus compounds. Starch and salt were added to both rations, and in all cases the rations were so balanced that the percentages of protein and carbohydrates were unchanged.

The results substantiate the evidence obtained by other observers, that whenever there is an insufficient supply of lime and phosphoric acid in the ration these compounds are withdrawn from the body, but are restored when a change is made to a ration rich in these compounds or when the deficiency is supplied in the form of dicalcium phosphate. If the deficiency continued for only a few days the flow of milk remained normal, but when continued for any length of time it rapidly decreased. The percentages of phosphoric acid and lime in the milk remain practically unchanged.

The action of animal extracts on milk secretion, E. A. Schäfer and K. Mackenzizie (Proc. Roy. Soc. [London], Ser. B, 84 (1911), No. B 568, pp. 16-22, figs. 3).—The authors studied the effect on the secretion of milk of a large number of animal extracts, including those of the placenta, uterus, fetus, pituitary body, mammary gland, duodenum, liver, spleen, kidney, thyroid, ovary, testis, thymus, and suprarenal capsules. Both cats and dogs were anesthetized
either with chloroform alone or with chloroform followed by chloral. The extracts, which in most cases had been boiled, were injected slowly and in small amounts into a superficial vein, and the flow of milk measured both by recording the rate of exudation of milk from a small and superficial cut into one of the mammary glands (exudation method), and by the nipple method, where a cannula was tied to a cut nipple. By both methods the milk was allowed to drop upon an electric recorder and the drops marked by an electromagnetic signal upon the paper of a kymograph. In some cases data on blood pressure, volume of the kidney, and rate of excretion of urine were recorded.

The most constant positive results obtained were from extracts of the posterior lobe of the pituitary body of the ox. The effect of the repeat dose on the secretion of the mammary gland was less than that produced by the first dose, and in some cases failed to be recorded by the nipple method, although it could sometimes be observed by the exudation method. The galactagogue substance of the pituitary body was not present in the pars anterior, but only in the pars intermedia and pars posterior of the gland. The galactagogue action ran parallel in time with the action of the extract upon the systemic blood vessels, which were contracted by the posterior lobe extracts. It is probable, however, that, as in the case of the kidney, the blood vessels of the mammary gland do not share in the general constriction which this extract produces. The extract of fresh corpus luteum from the sheep, prepared with Ringer’s solution, also yielded a definite positive result, but the effect was less decided than with the extract of the posterior lobe of the pituitary. The active substance is probably different, for its galactagogue action was unaccompanied by the same general rise of blood pressure.

To produce the galactagogue effect it was not necessary to employ a lactating animal, as in one instance a free flow of fluid of serous appearance was obtained from the incised mammary of a cat apparently virgin and not fully grown.

The galactagogue action of secretin, eserin, and nicotin was tested, but with negative results. A dose of pilocarpin induced intense salivation and lacrimation, but had no perceptible influence on milk secretion.

A note is appended to the article stating that since the above paper was read Dr. Mackenzie has found that extracts both of involuting uterine mucous membrane and of the mammary gland itself are markedly galactagogue and that with regard to the action of the pituitary extract the source of this extract appears to make no difference to its activity, the extract of the bird’s pituitary being quite as active in promoting the mammary secretion as that of the mammalian pituitary itself. He has also determined that atropin does not interfere with the action of any of these galactagogues.

*Mycology of milk, H. Weigmann (Mykologe der Milch. Leipsic, 1911, pp. XVI+267, figs. 94).—A general treatise on the fermentation of milk and the technique employed in the manufacture of dairy products.

The different sections treat, respectively, of (1) the morphology and biology of micro-organisms in general, (2) descriptions of important groups of bacteria, yeasts, and molds occurring in milk and its products, and (3) an application of the knowledge of these micro-organisms in the production of sanitary milk and in the manufacture of butter and cheese.

A combined milk can and sampler (Mühl. Ztg., 40 (1911), No. 24, p. 233, fig. 1).—A milk container is illustrated and described, a special feature of which is a perforated tube so constructed that samples of milk can be easily taken without pouring out the contents.

Notices of judgment (U. S. Dept. Agr., Notices of Judgment 905, 914, 979, 980, pp. 2 each).—These relate to the misbranding of cheese, and the adulteration and misbranding of condensed milk.

Pasteurization of milk in the bottle on a commercial scale, C. E. North (Med. Rec., [Y. V.], 80 (1911), No. 3, pp. 111-115, figs. 3).—In order to discover a method of preventing reinfection after pasteurizing, the author undertook experiments in pasteurizing milk after bottling and sealing with watertight caps. The pasteurizing was done by both the submerging and shower-bath types of pasteurizers, such as are used in breweries. In all cases a high degree of efficiency was obtained, and the author recommends this method of pasteurizing.

"The pasteurization of milk in the bottle on a large scale is entirely possible and practicable. The placing of milk in a glass bottle with a water-tight seal, followed by pasteurization of the entire package, guarantees against reinfection until the bottle is opened and will place the operation of pasteurization as such above criticism. The adoption of this method by the large milk dealer will, I am sure, be a great step in advance and not only give additional protection for the product, but will also give a guarantee to the milk consumer against milk-borne infections which has not existed up to this time."

"It is not customary in the brewing industry to cool bottled beer to the same degree that milk is cooled; consequently, pasteurizers of beer are not equipped for cooling to low temperatures. It is, however, only a matter of adjustment to make provision for such cooling as is required in the milk industry. The capacity of the large pasteurizers used for bottled beer is in every respect equal to the needs of the large milk dealer."

Cream raising with pasteurized milk, M. Kersten (Molk. Ztg. [Hildesheim], 25 (1911), Nos. 30, pp. 553-555; 31, pp. 567-569).—Pasteurizing milk for a short time at a low temperature (69° C.) caused the cream to rise more rapidly than in the case of raw milk. When the milk was held for some time at that temperature, or when heated to a temperature of 65° or over, the cream rose more slowly than in the unpasteurized milk. Pasteurizing at a temperature of 63° for a few minutes gave about the same results as when unbeated.

The isolation of Bacillus typhosus from butter, D. H. Bergey (Jour. Med. Research, 25 (1911), No. 1, pp. 231-233).—The author was able to pick out the colonies of B. typhosus from among the colonies of other bacteria in butter when grown on the Drigalski-Conradi agar and malachite green agar.

The control of pathogenic organisms in butter, J. N. Force (Cal. State Jour. Med., 9 (1911), No. 9, pp. 367-370, fig. 1).—A study of the vitality of pathogenic organisms in butter showed that the bacterial count of butter does not serve as a measure of the contamination of the product for the reason that bacteria decrease as the butter grows older. Standard agar plates showing a preponderance of molds over bacteria are a slight measure of the age of butter and lack of cleanliness of utensils.

A method is outlined for the municipal control for the production of market butter. Score cards are proposed for scoring market butter and butter-making establishments.

Regulations governing the manufacture of certified butter (Cal. State Jour. Med., 9 (1911), No. 9, p. 389).—These regulations were adopted by the California Association of Medical Milk Commissions in 1911.
Condensed milk in the Orient, L. M. Wood (Daily Cons. and Trade Rpts. [U. S.], 14 (1911), No. 202, pp. 929–932).—This report contains statistics on the increase of exports of condensed milk from the United States to China and Japan.

Investigations on the ripening of cheese, especially the defect known as "short cheese, F. W. J. Boekhout and J. J. Ott De Vries (Verslag. Landbouw. Onderzoek. Rijkslandbouwproefst. [Netherlands], 1911, No. 9, pp. 5–25; Molk. Ztg., Berlin, 21 (1911), Nos. 21, pp. 241, 242; 22, pp. 253, 254).—The data in this article have been previously noted (E. S. R., 21, p. 679).

A new revolving cheese-press table, M. Reinisch (Österr. Molk. Ztg., 18 (1911), No. 10, p. 151, figs. 3).—A cheese press is illustrated and described, the principal feature of which consists of a contrivance for turning the cheese.

VETERINARY MEDICINE.

A practical guide to the newer remedies, J. M. Fortescue-Brickdale (New York, 1910, pp. VIII + 273).—This is a review of the newer drugs, the composition of which has been published elsewhere, and a discussion in regard to their pharmacology. The drugs are mainly synthetic products.

Immunization with vegetable proteins, Wendelstadt and T. Fellmer (Ztschr. Immunitätsf., u. Exp., Ther., I, Orig., 8 (1910), No. 1, pp. 33–37; abs. in Chem. Abs., 5 (1911), No. 3, p. 530).—The tests were made with ordinary saline extracts of unknown composition obtained from peas, beans, cereals, and the foliage of the same plants.

Immunization of the rabbit against the poison of amanites, Radas and Sartory (Compt. Rend. Acad. Sci. [Paris], 151 (1910), No. 2, pp. 156–158, fig. 1; abs. in Chem. Abs., 4 (1910), No. 33, pp. 3255, 3256).—The juice obtained from the caps of a large quantity of poisonous mushrooms (Amanita phalloides and A. mappa), which were preserved with mustard essence, was injected into rabbits with the result that the minimum lethal dose was found to be 8 cc. The symptoms preceding death were gastrointestinal in nature and paralysis. Death occurred in about 24 hours. The continued injection of minimum doses of A. mappa produced an immunity, with the optimum point at 4 months, which enabled the animal to withstand many times the minimum fatal dose.

Analysis of Zygadenus intermedius ("death camas"), F. W. Heyl and L. C. Rainford (Jour. Amer. Chem. Soc., 33 (1911), No. 2, pp. 296–211; abs. in Analyst, 36 (1911), No. 421, p. 156).—As several species of Zygadenus are causing heavy stock losses in Wyoming, Montana, and other northwestern States, the authors made a proximate and toxicological analysis of the leaf, flower, bulb, and root of Z. intermedius. By using a modified U. S. Pharmacopeia method for assaying belladonna, the authors were able to isolate the following amounts of crystallizable alcoholic residues: Leaf 0.41 per cent, 0.28 per cent, and 0.26 per cent, and in the bulb, 0.39 and 0.24 per cent. The dried plant when ground gave off dust which was very irritating, and which the authors believe to be veratriline.

Qualitative and quantitative determination of castor-oil seeds in wheat feed meal, H. Miesener (Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 3 (1911), No. 4, pp. 269–273).—Wheat meal which was fed to 2 horses caused the death of the animals within 3 days. The author suspected the presence of castor-oil seeds in the feed and conducted precipitation and conglutination tests for the presence of ricinol. The results were positive. The author details the

methods used for their detection. The results of a feeding test with a horse and calf are also given.

Report in regard to the activities of the health department of the chamber of agriculture in the Province of Pomerania, 1909-10, Schmitt (Abs. in Centbl. Bakt. [etc.], 1. Abt., Ref., 49 (1911), No. 5, p. 129).—In the work in regard to bovine tuberculosis 300 barns containing 26,155 animals over 6 months old were examined for clinical and open tuberculosis. For the bacteriological tests 512 samples of milk, 36 samples of nasal secretion, 13 samples of vaginal and uterine secretions, 1 piece of mucus tissue from the vagina, 2 pieces of lymph gland from theudder, and 2 samples of feces were received.

Open tuberculosis was detected in 36 bovines by clinical measures and in 78 by bacteriological tests. It was distributed as follows: Out of 925 bulls (breeding) none were affected; of 16,183 cows 110, or 0.68 per cent; of 8,897 young bovines 3, or 0.03 per cent; and of 150 draying cattle and cattle reserved for fattening 1, or 0.67 per cent. Of these 114 diseased animals 56 had tuberculosis of the mammary gland, 56 tuberculosis of the lung, and 2 tuberculosis of the uterus or vagina.

For combating hemoglobinuria of bovines, the vaccine prepared at this institution was utilized, and among 4,456 animals the protective vaccination reduced the mortality and the disease to a very large extent.

In regard to the disinfection of goats' hides and hair, H. A. Gins (Desinfection, 3 (1910), No. 8, pp. 405-417; abs. in Centbl. Bakt. [etc.], 1. Abt., Ref., 48 (1911), No. 18, p. 567).—It was possible to destroy anthrax spores in hides and hair with a formaldehyde steam mixture at 60° C. under a diminished pressure (160 mm. of mercury) in Rubner's apparatus. The hides, however, were also destroyed by the process, although the bristles were not.

Sero-diagnosis of glands, F. K. Meyer (Amcr. Vet. Rec., 39 (1911), Nos. 2, pp. 176-188, figs. 2; 3, pp. 261-269).—This is a discussion of the agglutination test, deviation of complement test, precipitation test, and sero-anaphylactic test, with particular reference to the value and technique of the complement-binding or deviation test for glands in animals (E. S. R., 25, p. 181).

Interpreting the mallein reaction, W. N. Matvejeff (Abs. in Ztschr. Immunitätsw. u. Erpf. Ther., II, Ref., 3 (1910), No. 9, p. 889).—In a paper read before the Second Veterinary Congress at Moscow, 1910, the author, after discussing the numerous practical rules for conducting this test, points out the necessity of taking the temperature at least 4 hours before introducing the mallein, and then determining the temperature hourly, beginning at the seventh hour after the injection and continuing it the 7 succeeding hours.

The mallein is best introduced in the forebreast because of the fact that this region is a favorable anatomical one for observing the swelling which takes place. The characteristics of the typical swelling, which has a definite line of demarcation, are a very pronounced, hard, painful area which is very warm to the touch. The size is usually 15 by 15 cm. In normal horses a local swelling also takes place when mallein is injected, but it is not so large as that in the glandered animals.

The author points out that the focal reaction, in the sense of an exacerbation must not be overlooked, in interpreting the mallein reaction. If a doubtful result is obtained, the author recommends a second injection of mallein, but only after one month has elapsed.

Hog cholera in man, F. Erlen (Münch. Med. Wochenschr., 58 (1911), No. 6, p. 299).—The author reports the symptoms of a condition which was produced in 5 individuals (2 adults and 3 children) by the ingestion of the viscera obtained from 2 hogs suffering from hog cholera.
Endemic Mediterranean fever (Malta fever) in southwest Texas, T. L. Ferrenbaugh (Journ. Amer. Med. Assoc., 57 (1911), No. 9, pp. 730, 731).—It is stated that during recent years there have been a few cases of continued fever of long duration, frequent relapses, and a low mortality, in the Pecos River country of Texas. While stationed at Del Rio with the United States Army 5 cases of this affection came to the author’s attention. Agglutination tests made with Micrococcus melitensis were positive, while tests with Bacillus typhosus were negative. All 5 of the patients had worked in goat camps and 4 had drank goat’s milk.

The author considers it possible that the goats of the Pecos River country, and doubtless along other sections of the border, are infected with the M. melitensis. The drinking of goat’s milk in the Pecos River country is not common, except among Mexicans and those located at isolated goat camps, but the author was informed that along some sections of the border as much goat’s milk is drunk as cow’s milk, this being especially true for the Mexican population.

Studies in regard to the etiology of rabies, J. Koch (Ztschr. Hyg. u. Infektionskrank., 66 (1910), No. 3, pp. 453–455, pl. 1).—The author has continued the work previously noted (E. S. R., 21, p. 83), with the aid of Krogh’s new staining method.

With this he was able to verify his former conclusions, that the extra and intracellular cocci-like bodies observed in the gray substances of the brain and cord in rabies were not artifacts or products of degeneration, but definite forms which may have a relation to parasites. In some of the experimental quiet cases Negri bodies could not be observed. From this he concludes that some difference must exist between the disease produced artificially and that conveyed by the bite of the dog. He points out the various areas in which these formations are most likely to be found and the method for detecting them. He holds that the inner cocci-like formations of the ganglion cells and gray substance are identical with the inner formations of the Negri bodies, which are considered spores by Negri.

A new harmless, easy, and simple method for conducting the tuberculin reaction, P. Barabaschi (Gaz. Osped. e Clin. [Milan], 31 (1910), No. 94, pp. 987–989; abs. in Ztschr. Immunitätsf. u. Expt. Ther., II, Ref., 3 (1910), No. 12, p. 1053).—The method consists of strongly rubbing the area with absolute alcohol to produce a hyperemia and redness of the skin. In the center of this zone a thin layer of crude tuberculin is applied and then allowed to dry. The reaction when positive manifests itself by forming red, slightly raised blisters, which appear in from 24 to 72 hours.

The antiformin method for examining sputum, Sachs-Müke (Deut. Med. Wochenschr., 36 (1910), No. 7, pp. 320, 321; abs. in Hyg. Rundschau, 20 (1910), No. 21, p. 1171).—This is a comparative test between the antiformin and hydrogen peroxod methods for detecting tubercle bacilli. The results show that the first-named failed to detect the bacilli in two instances, while the latter showed their presence. The author believes that antiformin destroys the tubercle bacilli, and recommends the adoption of the hydrogen peroxod method.

Experimental investigations in regard to the virulence of old (inactive) tuberculous foci in bovines, B. Uhlenbrock (Experimentelle Untersuchungen über die Virulenz alter (reaktiver) tuberkulöser Herde beim Rind. Inaug. Diss., Univ. Beru, 1910, pp. 31; abs. in Internat. Centbl. Gesam. Tuberkulose Forsch., 5 (1911), No. 5, p. 234).—In old calcified foci tubercle bacilli could be noted. The bacilli, however, had undergone a certain amount of degeneration and showed a diminished virulence.
The elimination of tubercle bacilli from infected cattle, and the control of bovine tuberculosis and infected milk, V. A. Moore (New York Cornell Sta. Bul. 299, pp. 697-714).—This bulletin first describes the channels through which tubercle bacilli get into the milk of infected cows and the frequency with which market milk is found to contain them.

Numerous examinations were made in order to gain definite knowledge of the frequency with which this bacillus occurs in the milk and feces of cows that react to tuberculin. In preliminary work a total of 136 samples of milk and 36 of feces were examined. Of the milk samples, 49 were mixed and 87 were from individual cows, 2 with diseased udders. In all, 80 guinea pigs were inoculated, each receiving 2 cc. of the sediment from the centrifuged tube. Sixteen of the pigs were injected in the abdominal cavity, while the others received the sediment subcutaneously. The results of these examinations were as follows:

"Of the 49 examinations of mixed milk, tubercle bacilli were found in one specimen microscopically and no inoculations were made. Later experience suggests that possibly these were acid-fast organisms other than true tubercle bacilli. It was not known to us whether or not clinical cases existed in this herd. Guinea pigs inoculated with the mixed milk from 2 herds developed tuberculosis. In these herds it was known that there were clinical cases. After these were removed subsequent inoculations gave negative results. The guinea pigs inoculated with the samples from the other mixed milk either died within a few days from sepsis, or remained well. Thus there were 2 of the 49 samples that contained infecting organisms and possibly the third did also. This gives as the maximum a little over 6 per cent that contained tubercle bacteria.

"Of the 87 examinations of the milk from individual cows, tubercle bacteria were not found either microscopically or by guinea pig inoculations except in 2 cases, and these were samples of milk from the cows whose udders were affected. They were the only cows that showed any clinical evidence of disease, and at the time the lesions in the udders were not thought to be of a tuberculous nature. Tubercle bacilli were present in very large numbers in the milk from each of these cows. The bacilli were largely outside of the tissue cells, lying free between the leucocytes and fat globules of the milk. In 2 specimens acid-fast or timothy bacilli were present in very small numbers. They were decolorized with acidulated alcohol. Guinea pigs inoculated from these samples did not develop tuberculosis. If we exclude the 2 cases in which there was udder affection, tubercle bacteria were not found in any of the samples. If they are included, a little over 2 per cent of the examinations were positive.

"The 36 examinations of the feces failed to reveal the presence of tubercle bacteria, either microscopically or by animal inoculation. One specimen contained a few acid-fast organisms. The guinea pig inoculated from this specimen did not develop tuberculosis."

The results obtained from repeated examinations of milk and excreta of reacting cows, and from feeding the milk of such cows to young pigs during the time the milk and feces were being examined microscopically and guinea pigs were being inoculated, lead the author to conclude that "the spread of tubercle bacilli is not generally taking place, at least to any detectable degree, from occult cases of bovine tuberculosis. The evidence thus far gathered is quite as conclusive that cows with udder tuberculosis are eliminating tubercle bacilli in large numbers with their milk, and that advanced cases of pulmonary tuberculosis, or perhaps earlier ones in which the lesions are discharging into the
bronchi, and cases of intestinal lesions are eliminating them with the drooolings from the mouth and with the feces.

"The presence of tubercle bacilli in milk seems to be accounted for by tuber-
culous udders and from contamination of the milk with the feces. When these
facts are applied to the milk situation it seems fair to assume that if the cows
in the dairies producing milk for the market were carefully and frequently
examined for evidence of the disease and all those found to be thus affected
were excluded the number of samples of market milk containing tubercle bacilli
would be greatly reduced if they did not entirely disappear."

The author states that a careful and often repeated physical examination of
infected herds and the removal of all suspicious cases will check to a large
extent the spread of the disease to other animals in the herd and will minimize
the number of bacilli in the milk, thereby protecting the consumer. However,
to prevent the interherd spread of the disease tuberculin must be properly
applied to all cattle coming into sound herds.

The International Commission's recommendation on eradication, a full report
of which has been previously noted (E. S. R., 25, p. 384), is appended to the
bulletin.

The elimination of tubercle bacilli from infected cattle, V. A. Moore (Jour.

The treatment of contagious granular vaginitis in cattle, A. Laszlo (Vet.
Jour., 67 (1911), No. 334, pp. 484, 485).—The author has obtained successful
results from the use of "Bissulin," a mercury preparation.

Experimental prophylaxis for distomiasis, A. Railliet, G. Moussu, and A.
Henry (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 11, pp. 425-427).—In
tests made of the resistance of the ciliated larvae of the liver fluke to various
chemicals used as fertilizers, etc., including gypsum, lime, iron sulphate, and
the nitrates, sulphates and chlorids of potassium and sodium, it was found that
the larvae were manifestly more susceptible to the action of sodium salts than
to those of potassium. Agricultural lime, however, was found to be the most
destructive agent tested, immediate destruction following the use of 3 gm. of
lime to a liter of water, or 0.75 parts in 1,000. In order to be effective liming
should be done in the spring or in summer.

In experimenting with small undetermined species of snails, it was found that
they were destroyed when exposed for 5 minutes to a solution of 0.5 parts of
lime in 1,000.

Experimental treatment of distomiasis, A. Railliet, G. Moussu, and A.
Henry (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 11, pp. 427-429).—In
the attempt to destroy the liver fluke while in the liver, the authors used aloes,
calomel, sodium salicylate, and boldo. The greater number of the animals
affected were benefited by the treatment, but the parasites were not destroyed,
as was determined at post-mortem examination. Other experiments in which
phosphorated oil, arsenic, atoxyl, dioxydiamidoarsenobenzol, trypanblue, ben-
zoate of mercury, and fluid extract of genista (scoparius) were employed, were
without positive results.

Researches on the treatment of distomiasis of the sheep, A. Railliet, G.
Moussu, and A. Henry (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 17,
pp. 1125-1127; Rec. Méd. Vét., 88 (1911), No. 9, pp. 283-289; Vet. Rec., 24
(1911), No. 1200, pp. 17-19).—Severe losses of cattle in France during the early
months of 1911 led to the investigations of the liver flukes here reported.

In attempting to find an agent that will destroy the flukes in the bile ducts,
the authors experimented with aloes, calomel, sodium salicylate, "boldo," tartar-
emetic, urotroope, and atoxyl, with negative results. They were more success-
ful in experiments with ethereal extract of male shield fern.
It was found that the large fluke, *Fasciola hepatica*, and the small fluke, *Dicrocelium lanceatum* seu *demodictum*, manifested a very different resistance to the action of drugs. The experiments indicate that the ethereal extract of male shield fern acts only on the large flukes and exclusively on those of the liver, the flukes which have migrated to the peritoneal cavity not being affected. Four doses of 5 gm. each appear to be required in order to assure the success of the treatment.

Protective vaccination against swine plague, Ruß (Mitt. Ver. Bud. Tierärzte, 10 (1910), No. 5, pp. 76, 77; abs. in Centbl. Bakt. [etc.], 1 Abt., Ref., 49 (1911), No. 5, pp. 154, 155).—The author points out that the bivalent serum of Klett-Braun is a good one, but that on account of its price its use is not always possible.

Researches in regard to "esponja," a disease which affects solipeds in certain parts of Brazil, P. Ferret, A. Dupuy, and L. Mercier (Compt. Rend. Soc. Biol. [Paris], 69 (1910), No. 38, pp. 654–656, pls. 2; abs. in Centbl. Bakt. [etc.], 1 Abt., Ref., 49 (1911), No. 5, p. 135).—Among horses in Brazil a disease was noted which was characterized by the formation of nodules in the skin which went over to pus formation. The nodules were found to contain a nematode, which is described, and some yeast-like bodies. The authors were in doubt as to which of the two was the causative agent.

[Report of] veterinary department, L. Van Es (North Dakota Sta. Rpt. 1909, pp. 37, 98).—The author states that studies of infectious anemia of the horse conducted during the year show conclusively that an infected horse may die of the disease without any reduction of the red blood corpuscles, that certain cases may run along for considerable periods without an elevation of the body temperature, that such horses, although they fail to present any clinical evidence of the disease, still carry the infectious agent, and that when small quantities of their blood are injected into normal horses the disease is promptly reproduced.

[Report of] veterinary department, L. Van Es (North Dakota Sta. Rpt. 1910, pp. 55–57).—A brief summary is presented of investigations of swamp fever conducted during the year ended February 28, 1911, the detailed results of which were awaiting publication.

A study showing bacteria and animal organisms determined in the feces and intestinal mucosa of healthy chickens, G. E. Gage (Maryland Sta. Bul. 153, pp. 201–226).—Three observations were made upon the feces of each of 45 birds ranging in age from 1 day old up to 2 years. Observations were also made upon the intestinal mucosa of 60 birds, including birds taken from the shell, newly hatched chicks, and fowl ranging in age up to 2 years.

It was found that the intestinal flora of healthy domestic fowls vary to some extent with the conditions of poultry environment and different stages of life.

"It may be stated that approximately 60 per cent of the organisms in the domestic fowl do not stain by Gram's method, and that under ordinary conditions of poultry environment approximately 40 per cent are gram-negative in their staining reactions. The *Bacillus coli* type of organisms represent the larger part of the gram-negative percentage.

"The intestinal mucosa of the healthy domestic fowl may harbor a large and varied flora which is constant only to a certain extent. Few obligatory anaerobes are present.

"*B. coli* was the preponderating organism in the intestinal mucosa and the feces, and undoubtedly it plays the same rôle physiologically that it does in the alimentary canal of higher animals. Since it is so omnipresent it is undoubtedly an obligate bacteria, and under some circumstances renders service by producing
conditions which discourage the growth of many harmless and harmful species which the bird can not exclude readily.

"The absence of large numbers of obligatory anaerobes of the B. putreficans type would indicate that the intestinal conditions in the healthy domestic fowl are not inducive for anaerobiosis.

"Chickens reared under sanitary conditions do not harbor many animal organisms. In several subjects in the best of health Euglena and Paramecium caudatum were found by examinations of fresh preparations. Heterakis worms and tapeworms are found in healthy birds, but their presence must be looked upon as indicative of some unsanitary condition in the poultry yards. They may cause intestinal lesions, which may later be the starting point of more serious infections. Tapeworms in small numbers, according to observations made after death, do not appear to cause serious pathological effects.

"The presence of Cladothyris asteroides in the intestinal mucosa has not in any instance appeared to be pathogenic for the domestic fowl in any stages of its life."

Is it tuberculosis?—An important question, G. B. Morse (Rel. Poultry Jour., 18 (1911), No. 6, pp. 778, 828, 839).—As a result of examining the caseous matter present within the lids of a roupy black Minorca fowl it was found to contain numerous acid-fast bacilli, which, however, were not alcohol acid-fast and were not morphologically characteristic of the bacilli usually found in tuberculosis of fowls. They were short, generally slightly curved, pointed at both ends, and rarely headed.

A bacillus of the same kind was found in nodules on the wing, beneath the eyes, etc., of pigeons (pigeon disease). Some of the material was inoculated into a pocket made beneath the conjunctiva of the right eye of a pullet and into the right eye of a young pigeon, and with another pigeon into a subcutaneous pocket in the right side of the neck. In about 5 days a lump was produced in each case, from which the characteristic bacilli were isolated.

According to the author, "it therefore appears that this quite common disease of pigeons, usually pronounced tuberculosis on account of finding acid-fast bacilli in the cheesy material, must be recognized as a pseudo-tuberculosis."

Tests with Wech's vaccine (gallin) against fowl diphtheria, Zeh (Laufe, Wehnschr. Sachsen, 12 (1910), No. 6, p. 44; abs. in Berlin. Tierärztli. Wehnschr., 27 (1911), No. 12, p. 210).—This preparation did not yield good results.

RURAL ECONOMICS.

A study of farm equipment in Ohio, L. W. Ellis (U. S. Dept. Agr., Bur. Plant Indus. Bul. 212, pp. 57, figs. 4).—This bulletin presents the results of a study of farm equipment, under the joint auspices of the Office of Farm Management of this Department and the department of cooperation of the Ohio Agricultural Experiment Station, on a number of Ohio farms where conditions were unusually favorable for obtaining information as to the proper relationship between investments in land, improvements, live stock, machinery, tools, and other farm equipment. Considerable data and a number of tables are presented illustrating the distribution of investments and showing the approximate cost and value of many items which serve to illustrate by concrete examples many of the factors to be taken into consideration in equipping farms. Other tables show the average area and the volume of space devoted to live-stock enterprises, and the storage of products, machinery, etc., in buildings, and the cost, value, and number of rods of fencing per acre on each of 21 successful farms.

As to the distribution of acreage by enterprises it is shown for the group of 21 farms, with an average size of 165.88 acres, that each has an average of

1254°—No. 7—11—7
5.51 acres included in lots, lanes, waste spots, public roads, and other lands belonging to the farm which can not be properly charged to any other enterprise or group of enterprises; 2.04 acres in dooryard, family garden, and orchard, when not grown as a commercial proposition; 0.08 acre in tenant yards, gardens, etc.; 46.5 acres in lots, pastures, and fields devoted exclusively to live stock; $5.71 acres in tilled and mowed fields; 2.98 acres in permanent groves maintained largely for the production of maple sugar or sirup; 1.95 acres in fruit orchards largely commercial in their nature; and 21.11 acres in woodland. The mean average in crops is shown to be 52.8 per cent.

The first cost of equipping an average farm in Ohio is approximated as follows: Land, 105.88 acres at $46.25 (average) per acre, $7,676.42; farm buildings, $2,700; household buildings, $2,500; fences, $763.74; drainage, $300.43; water supply, $225; work animals, $640.71; colts and driving horses, $250.95; cattle, $582.26; sheep, $201.05; swine, $158.34; poultry, $52.60; bees, $3.23; harness, $131.05; machinery, $1,125.48; minor articles, $200; produce, supplies, etc., $631.93; total, $18,299.19. Of course, this applies only to farms equipped outright with new buildings, fences, machinery, etc.

The average cost per acre per year of machinery, which is represented by the sum of depreciation, repairs, and interest, is shown to be as follows: Walking plow, $0.072; ridgling (or gang) plow, $0.183; spike harrow, $0.019; spring harrow, $0.027; disk harrow, $0.049; roller, $0.02; plinker or drag, $0.008; weeder, $0.063; corn planter, $0.061; 1-horse cultivator, $0.043; 2 or 3 horse cultivator, $0.041; corn binder, $0.369; corn shocker, $0.843; grain binder, $0.364; grain drill, $0.13; hay loader, $0.248; mowing machine, $0.105; hay rake, $0.055; and tedder, $0.104.

A study of farm equipment, L. W. Ellis (Ohio Sta. Bul. 227, pp. 203-253, figs. 4).—Noted above.

Farm machinery (Wyo. Farm Bul., 1 (1911), No. 2, p. 31).—The economic significance of important farm machinery generally is discussed, and the belief expressed that it is not only cheaper than manual labor, but will do the work better in most cases. A loan system inaugurated at the Wyoming Experiment Station is described, by which manufacturers loan farm machinery of various kinds to the station for use in public inspection, demonstrations, and experimental work on the station lands.

Cost of growing crops in Nebraska, C. W. Pugsley (Nebraska Sta. Bul. 122, pp. 3-12).—The data reported in this bulletin were secured by correspondence with a large number of farmers in various parts of the State and are given as an indication of the cost of production of the most common farm crops on an average Nebraska general-purpose farm.

The following table summarizes data as to the average cost of growing corn, wheat, oats, wild hay, clover, and alfalfa, including interest and taxes and the time for men and teams while in the field, but not including marketing:

<table>
<thead>
<tr>
<th>Kinds of crop</th>
<th>Yield per acre</th>
<th>Cost per acre</th>
<th>Cost per bushel or per ton</th>
</tr>
</thead>
<tbody>
<tr>
<td>Corn</td>
<td>39.30</td>
<td>$11.63</td>
<td>$0.296</td>
</tr>
<tr>
<td>Wheat</td>
<td>22.20</td>
<td>$12.19</td>
<td>$0.549</td>
</tr>
<tr>
<td>Oats</td>
<td>35.00</td>
<td>$11.39</td>
<td>0.325</td>
</tr>
<tr>
<td>Wild hay</td>
<td>1.25</td>
<td>$6.72</td>
<td>5.370</td>
</tr>
<tr>
<td>Clover</td>
<td>2.04</td>
<td>8.54</td>
<td>4.180</td>
</tr>
<tr>
<td>Alfalfa</td>
<td>3.33</td>
<td>10.33</td>
<td>3.100</td>
</tr>
</tbody>
</table>
It was found that the two greatest factors in influencing the cost per bushel or ton were the price of land and the yield per acre. At the average market prices the most profitable crops considered were wheat, corn, and alfalfa.

The average cost of growing crops in Nebraska, C. W. Pugsley (Independent Farmer, 44 (1911), No. 50, pp. 787, 788).—A popular summary of the above.

A successful New York farm, M. C. Burritt (U. S. Dept. Agr., Farmers' Bull. 454, pp. 32, figs. 9).—This is the story of the struggles and successes on 57 acres of land of a plain New York farmer, who began with the common drawbacks, such as indebtedness, lack of capital, run-down land, poor drainage, etc., but who, by applying systematic methods to the farm and by thorough organization of the business, converted it into an example of profitable farming. The method of organization of the farm, preparation of the land, fertilization, seeding, planting, cultivation, harvesting, marketing, and general results are fully set forth and illustrated. The pursuance of a well-developed systematic plan is considered the secret to his success.

Agriculture in the central part of the semiarid portion of the Great Plains, J. A. Warren (U. S. Dept. Agr., Bur. Plant Indus., Bul. 215, pp. 43, figs. 4).—This bulletin presents a study and discussion of the management of "dry farms" and the problems confronting the farmers of the semiarid portion of the Great Plains, changes in the economic conditions, the climate, precipitation, evaporation, effect of wind on agriculture, soils, farm practices in the region, improved methods of tillage, and the introduction and development of drought-resistant crops.

It is pointed out that on the better lands near the eastern limit of the territory 320 acres should be sufficient to support a family, but that near the western limit from 2 to 4 sections would be needed. It is not considered a place where one should expect to make large profits on small farm investments, "No man should go empty handed into this country, but many men with limited means who are willing to endure some privations will be able to secure a foothold and establish homes." It is suggested that from $6,000 to $8,000 should buy enough land to support a family of average size, and that where it is simply a stock proposition $50 should buy enough land to pasture 1 cow.

Suggestions to settlers on the Belle Fourche irrigation project, B. Aune (U. S. Dept. Agr., Bur. Plant Indus., Circ. 83, pp. 1/).—This circular presents suggestions to settlers on the Belle Fourche irrigation project, giving a description of the region, and notes on the treatment of sod land, preparation of the seed bed, adaptability of various crops and fruits to the soil, methods of culture, tree planting for windbreaks, methods of irrigation, publications of value, etc.

Large and small holdings, H. Levy (Cambridge, 1911, pp. VIII+240).—This is an English edition of a work previously noted (E. S. R., 16, p. 108), to which have been added a discussion as to the modern small farmer and the question of home colonization, tables showing the area of agricultural land under the various types of holdings throughout the English counties, and a lengthy bibliography.

Agricultural cooperation, S. E. Todd (Ontario Dept. Agr. Bul. 192, 1911, pp. 52).—This bulletin presents a discussion as to the historical development and fundamental principles of agricultural cooperation, and illustrates by concrete examples its practical application in dairying, fruit-marketing, and simi-
lar societies in Canada, the United States, and foreign countries. A set of by-laws recommended for adoption in the formation of such societies is appended, together with a list of cooperative fruit growers' associations in Ontario in 1911.

Rural Denmark and its lessons, H. R. Haggard (London and New York, 1911, pp. XI+335, pls. 16).—This book presents data gathered by the author while inspecting Danish farms of various sizes. In addition to many other phases of rural life discussed and illustrated it treats of the following subjects: Credit union banks; the state small holdings; the economic position of Danish agriculture; cooperation in Denmark; societies for purchase and sale; and the State and its relation to agriculture in Denmark.

Cooperative agriculture in northern Holland, D. P. De Young (Daily Cons. and Trade Rpts. [U. S.], 14 (1911), No. 206, pp. 1010, 1911).—The report shows that one of the most important features of the agricultural industry in northern Holland is the tendency toward cooperation. Instead of being either national or provincial in character, as the associations were 10 years ago, and dealing with theoretical problems and ignoring the more vital matters of practical farm life, they are administering more to local needs, such as cooperative buying, credit, insurance, education, and general social uplift, gradually approaching a state of mutual cooperation. In connection with the general organizations there are numerous societies for special purposes, such as dairying, fertilizers, cattle breeding, farm administration, household economics, and a great diversity of other problems.

The report shows that the membership of the provincial farmers' associations numbers 56,000, agricultural societies 31,500, stock growers' organizations 2,400, and various rural cooperative societies 38,000. The value of the goods purchased by these societies in 1907 was $7,477,200, as compared with $4,776,162 in 1904. In the last decade the increase in agricultural products in this section has been about 75 per cent, attributed largely to the system of cooperation.

The banker and the farmer (Wallaces' Farmer, 36 (1911), No. 24, p. 938).—This article calls attention to the increased interest in farming manifested by bankers, showing that the bankers of the central West have interested themselves in promoting corn contests, short courses, institutes, and other activities which tend to raise the grade of farming. As an illustration is cited the recent proposition by the Jersey State Bank, Jersey, Ill., which proposes to loan any farmer as much as $3,000 on approved notes without interest, until after the harvest of 1912 for the purchase of commercial fertilizers or ground limestone to be used on wheat ground this fall.

[Rural economics—discussions] (N. Y. Dept. Agr. Bul. 23, pp. 261–473).—This bulletin gives the proceedings of the seventy-first annual meeting of the New York State Agricultural Society. Among the papers are the following: Feeding Our People of the Future, by N. P. Hull; The Development of Our Agricultural Resources and the Relation Between this Problem and the Cost of Living, by R. A. Pearson; Relation of Railroad Rates to the Prices of Farm Products, by Ira Shoemaker; and Farmers' and Consumers' Prices of Farm Products, by George K. Holmes. A report of the committee on the marketing and transportation of agricultural products and a general discussion of this topic are also included.

Crop Reporter (U. S. Dept. Agr., Bur. Statis. Crop Reporter, 13 (1911), Nos. 7, pp. 49–66; 8, pp. 57–61, figs. 2; 9, pp. 63–72, figs. 2).—Notes and statistics are given on the condition of crops in the United States and foreign countries, a comparison of conditions at corresponding periods for a number of years, farm values and range of prices of agricultural products in the United States, monthly
receipts and stocks of eggs and poultry in the United States, monthly movement of grain from the farms, temperature and precipitation statistics, and other data.

Foreign crops, July, 1911, C. M. Daugherty (U. S. Dept. Agr., Bur. Statis. Circ. 21, pp. 15).—This circular reports the acreage and condition of the principal crops in foreign countries in July, 1911, the prospective yields compared with actual yields last year, and the imports and exports of wheat and wheat flour in several foreign countries.

Tobacco report, July 1, 1911, J. P. Killebrew (U. S. Dept. Agr., Bur. Statis. Circ. 22, pp. 8).—This circular reports the acreage and condition of tobacco in the United States July 1, 1911, by States and districts, with comparisons with previous years. The area of cigar-leaf tobacco is shown to be 154,200 acres against 146,200 acres last year, an increase of 5.6 per cent, while in the chewing, smoking, snuff, and export districts the area is 730,000 acres compared with 1,070,100 acres last year, a decrease of 31.7 per cent.

AGRICULTURAL EDUCATION.

A study of 15 consolidated rural schools; their organization, cost, efficiency, and affiliated interests, G. W. Knorr (Washington, 1911, pp. 55, figs. 18).—This is a report covering a study tour by southern state superintendents of schools in communities having successful consolidated rural schools, with a view to learning at first hand the financial, agricultural, and social conditions under which consolidation of schools was effected in the respective localities, the degree of development of this new form of rural schools, how far the schools meet the needs of the rural communities which they serve, and to what extent the schools, once permanently established, enter the rural community life, become part of it, and prepare its youth vocationally for life's work. The 15 schools included in the itinerary are located in Montgomery and Tippecanoe counties, Indiana, Trumbull county, Ohio, and one in Maryland. The total enrollment was 2,381 pupils, of which 501 were in the high school, representing a total rural population of approximately 14,300.

It is reported that these communities have demonstrated to their own satisfaction that consolidated schools more fully meet their needs than the small district schools which were displaced. The schools have now so completely become a part of the respective communities "that none would for an instant entertain the proposition to abandon them and return to the small detached schools of former days."

The statistical data included in the publication afford information as to (1) the location of buildings, their cost, and average distance from homes; (2) the annual total expenditures for the maintenance of the schools, for the conveyance of pupils, and the cost of schooling per pupil per day; (3) the number and kind of teachers, and the number of district schools merged; (4) the organization of the school wagon service, the size of districts maintaining such service, and the enrollment and average attendance of pupils.

A review of the observations made by the visiting superintendents brought out the theory "that consolidation seldom proceeds successfully without the approval and general support of the community concerned."

The teaching of agriculture in the secondary schools, L. Anderson (Univ. Cal. Chron., 13 (1911), No. 2, pp. 161-176).—In this address the question as to what is agriculture is discussed, and reasons are given for teaching it. Among these are (1) that the youth may be brought to appreciate the value of small things, (2) for the contentment which it brings, and (3) its usefulness.
The 2 general methods employed in presenting agriculture to pupils of secondary grade, viz, in the special and in the regular schools, are considered closely.

The 60 acres of land connected with the school grew about enough grain and forage the first year to keep 3 horses, but the third year saw $94! left after paying every dollar that went into seed, fertilizers, and labor. This increase, according to the dean of the school, has had more to do with putting the institution on its feet than all the talking he could do.

A year of agriculture in a rural Vermont high school, H. A. Farrar (Middlebury [Vt.] Col. Bul. 5 (1911), No. 5, pp. 44).—The exercises which have formed the basis of the first year in agriculture in a typical rural Vermont high school are here presented. There are 22 exercises on soils and fertilizers with one or more references after each. The major portion of the volume is taken up with an annotated bibliography of agricultural education literature.

[Agricultural and forestry education in Australia] (Lond u. Forstw Unterrichts Ztg., 23 (1909), No. 3-4, pp. IV+107-310).—This report contains (1) special papers as follows: The Importance of Commercial Instruction at the Agricultural and Forestry Schools; Modern Agriculture in its Relation to Natural Science and Technology, by Franz Schindler; Practicums in the Secondary Agricultural School Course, by Rudolf Wessely; Preliminary Practical Work in Forestry and Practical Instruction in the Lower Forest Schools, by Karl Pusch; Instruction in Political Science at Technical Educational Institutions, by Ludwig Fleischner; Training our Girls in Housekeeping, by Franz Brosch; Present Status and Organization of Agricultural and Forestry Schools in Germany; Regulating the System of Agricultural Apprenticeship in Germany; and Report on Rural Continuation Schools in Prussia; (2) a review of agricultural literature and book notices; (3) a summary of the annual reports of the agricultural and forestry schools for 1908-9; and (4) miscellaneous notes.

The organization and development of agricultural, industrial, and commercial instruction in Egypt, S. H. Wells (Egypte Contemporaine, 1911, No. 7, pp. 314-309, dyns. 4).—This is a study, prepared at the request of the president of the Khedivial Society of Political Economy, Statistics, and Legislation with the sanction of the minister of public instruction, to show particularly how agricultural, industrial, and commercial instruction is administered, its aim, recent progress, and future development.

The only schools in Egypt giving instruction in agriculture at present are the school of agriculture at Ghizeh and 3 industrial schools with agricultural sections at Damamhour, Tough, and Luxor, but local contributions to the amount of $289,165 have been made for the erection and equipment of industrial and agricultural schools. All of these schools are under the control of the minister of public instruction, who received for the department of agricultural and technical education an appropriation for the current year of about $450,000, of which $41,521 was for schools.

Agricultural winter schools, J. B. Guillou (Bul. Mens. Off. Recenseig. Agr. [Paris], 10 (1911), No. 3, pp. 419-432).—This report on the organization and services rendered by the agricultural winter schools in France was made in response to a request from the minister of agriculture before authorizing an increase in the number of such schools. The author gives a general outline of the aim and definition of agricultural winter schools, brief notes on those in Ger
many, Austria, and the Netherlands, and more detailed information on the organization and development of these schools in France, together with detailed accounts of the organization, budget, employment of time, subject matter, etc., of individual winter schools located in lyceums, colleges, professional schools, etc.

Report of the work of the school gardening association in 1909 and 1910 (Bcr. For. Skotchar. Virks. [Denmark], 1909-1910, pp. 38, map 1).—This report contains a brief summary of the school-garden work in Denmark in 1909 and 1910, followed by accounts of the work of individual gardens, statements of receipts and expenditures of the association for 1909 and 1910, and a map showing the location of the school gardens, of which there were 55 in the spring of 1911.

Manual of agriculture for the public schools, State of Vermont, G. L. Green, L. C. Cook, and T. J. Abbott (Montpelier: Dept. Ed., 1911, pp. 16).—This manual consists of elementary exercises which require only simple apparatus for their performance, with explanations and observations. The general outline of the exercises includes the object, materials, directions, observations, conclusions, and references. The subjects treated are soils, plant life, plant growth, field crops, forestry, animal life, and score cards for potatoes, vegetables, cheese, butter, and dairy cattle. A list of a few desirable books is given at the close of the manual.

Agricultural geography in the high-school course, P. Hillmann (Fühlings Landw. Ztg., 60 (1911), No. 9, pp. 289-297).—This article discusses the need of instruction in agricultural geography in high schools; the subjects it should include, such as (1) the most important natural fundamentals—climate, the agricultural value of a country with reference to its natural vegetation and soils, and (2) the economic fundamentals—commercial conditions, labor, and credit; several methods of grouping this subject matter for purposes of instruction; and suggestions concerning literature.

MISCELLANEOUS.

Twentieth Annual Report of North Dakota Station, 1909 (North Dakota Sta. Rpt. 1909, pp. 99, figs. 2).—This contains the organization list, a brief report by the director, departmental reports, of which the experimental work is for the most part abstracted elsewhere in this issue, and a financial statement for the fiscal year ended June 30, 1909.

Twenty-first Annual Report of North Dakota Station, 1910 (North Dakota Sta. Rpt. 1910, pp. 59).—Data similar to the above are reported for the fiscal year ended June 30, 1910.

Experiment Station Work. LXIV (U. S. Dept. Agr., Farmers' Bul. 457, pp. 24, fig. 1).—This number contains articles on the following subjects: Low-grade fertilizers, Japanese cane for forage, fighting the boll weevil by clean farming methods, hastening maturity of cotton with fertilizers, the Scuppernong as a profitable crop, early spring lambs in the South, the production of sanitary milk, lacto—a new and healthful frozen dairy product—and a reenforced brick silo.
NOTES.

Arkansas University and Station.—G. A. Cole has resigned as professor of agricultural education and superintendent of farmers' institutes to become principal of the State Agricultural School at Russellville. The farmers' institutes in the future are to be in the immediate charge of the dean of the college. W. Lenton, professor of veterinary science and veterinarian, is no longer connected with the institution.

The first of a series of agricultural trains is to be run over the Frisco Railroad in December. It is planned to make half-day stops rather than hour stops as formerly.

California Station.—F. M. Hayes, of the Kansas Station, has accepted a position as assistant veterinarian.

Colorado Station.—G. P. Weldon has resigned as field agent at Grand Junction to become deputy state entomologist at Fort Collins.

Delaware College and Station.—Dr. M. T. Cook has resigned as plant pathologist to become professor of plant pathology in Rutgers College and plant pathologist in the New Jersey College Station. Dr. Raymond C. Reed has accepted the position of professor of veterinary science in the college and veterinarian in the station.

Florida University and Station.—A total appropriation of $165,000 was made to the university for the ensuing biennium, of which $30,000 was for a new building for the college of agriculture and $15,000 for farmers' institute work. Dr. E. W. Berger resigned as station entomologist July 1 to become state inspector of nursery stock, and has been succeeded by J. R. Watson, of the department of biology of the University of New Mexico. W. Voorhees has succeeded Mrs. Berger as librarian. Owen F. Burger has been appointed assistant plant pathologist. J. B. Griffith, of Southerland College, and F. M. O'Byrne, of Miami University, have been appointed laboratory assistants in plant pathology and plant physiology, respectively.

Idaho University.—H. A. Wadsworth has been appointed assistant professor of forestry in the school of forestry.

Illinois University and Station.—Courses have been added in farm accounting, the economic history of agriculture, and poultry husbandry. A wing 120 by 20 feet of the proposed poultry house has been erected, and 20 acres set aside for the use of the new department. D. O. Barto, formerly instructor in agriculture for secondary schools, has been appointed associate professor of poultry husbandry, and will have charge of the poultry work.

Recent appointments in the department of dairy husbandry include W. Truman Crandall, a graduate of the University of Missouri and for two years in charge of dairy husbandry work in Alfred University, as instructor in milk production; H. E. McNatt, of the Missouri University and Station, as instructor in municipal and sanitary dairying; R. S. Hulce, a graduate of the University of Wisconsin, as assistant in milk production; J. P. Terry, a graduate of Cornell University, as assistant in dairy manufactures; and F. E. Jorgensen as dairy field assistant.
Other appointments include W. F. Handschin, of the Minnesota University and Station, as assistant animal husbandman; Sleeter Bull as assistant in animal nutrition; Fred Bauer as assistant in soil fertility; Dr. W. B. Gernet as assistant in plant breeding; Harry W. Anderson as assistant in pathological floriculture; and Miss Cora Gray and Miss Pauline Wurster as instructors in household science. F. C. Granus has resigned as assistant in soil fertility to assume charge of the agricultural department of McKendree College.

**Kansas College and Station.**—Drs. E. C. Miller and N. E. Stevens have been appointed instructors in botany in the college and assistant plant physiologist and assistant plant pathologist, respectively, in the station.

**Michigan College and Station.**—Dr. William H. Brown has resigned as research assistant in plant physiology to become plant physiologist of the Philippine Bureau of Science, and has been succeeded by Dr. R. P. Hibbard, of the Mississippi College and Station.

**Montana College and Station.**—D. C. Cochran, assistant chemist since August 1, has returned to the Pennsylvania Institute of Animal Nutrition. W. F. Schoppe has been granted leave of absence for one year and has accepted a position as instructor in animal industry at the University of Maine, where he will also engage in graduate work.

**Nebraska University.**—Val Keyser has resigned to engage in practical horticulture in eastern Nebraska. C. W. Pugsley has been appointed head of the agricultural extension department, also retaining charge of investigations in farm management.

**New Hampshire College.**—J. H. Foster, of the Forest Service of this Department has been appointed professor of forestry, and has entered upon his duties.

**New York State Station.**—Rudolph J. Anderson has been appointed associate chemist and Orrin B. Winter, of the Michigan College, assistant chemist.

**Cornell University and Station.**—The extension work in the college of agriculture, for which the State has appropriated $50,000, is to be administered by special officers in the various subject matter departments, and also by a separate department of extension teaching. This separate department is to have charge of such publicity and organizing work as does not fall to the subject matter of the different departments, such as lecture courses, reading courses, itinerant schools, farm trains, and the like. Clyde H. Myers is to be extension instructor in plant breeding, R. P. Trask assistant in extension work in poultry husbandry, E. R. Minns assistant professor in extension work in farm crops, and Mrs. Ida S. Harrington instructor in extension work in home economics.

The work in farm management has been organized as a separate department, with G. F. Warren as head, K. C. Livermore as assistant professor, and A. L. Thompson as instructor. The work in farm crops has been united with the department of farm practice and is in charge of Prof. J. L. Stone.

The department of entomology is now known as the department of entomology, biology, and nature study, with Prof. J. H. Comstock as head of the department; Dr. J. G. Needham professor of general biology, limnology, and nature study; Dr. W. A. Riley assistant professor of entomology; Glenn W. Herrick assistant professor of economic entomology; James C. Bradley assistant professor of systematic entomology; and Anna B. Comstock lecturer in nature study, together with a number of assistants and instructors.

In the department of plant pathology D. Reddick has been advanced to a full professorship. M. F. Barrus has been made assistant professor in extension teaching, and Charles Gregory assistant in grape-disease investigations.

E. O. Fippin is to have charge of the extension work in soil technology, particularly of the soil surveys. Other changes include the advancement of
assistant professors White, Needham, Fleming, Love, and Gilbert to full professorships, and Messrs. Knudson and Beal to assistant professorships. E. Gorton Davis has been appointed assistant professor of rural art and Ray E. Deuel instructor in animal husbandry. A department of rural education is in process of organization, as is also a department of meteorology in its relations to agriculture.

Two buildings are under construction, the home economics building, for which the State has appropriated $154,000, and the poultry building for which $90,000 is available. Plans are being prepared for an auditorium for which $138,000 is authorized, a heating plant to cost $50,000, and a general horse barn to cost $20,000. To make room for the home economics building the old college barns, built many years ago by Professor Roberts, have been taken down. A temporary farm mechanics laboratory has been constructed and an amphitheater for outdoor classes erected in the park in the rear of the college buildings.

The publication of the *Announcer of the College of Agriculture* has been begun. This is to be issued monthly with a view to acquainting the people of the State with the work in progress. It will contain notes on investigations and extension enterprises under way, suggestions as to work in rural schools, reading courses, and other lines of interest. A specific object in view is the inclusion of brief summaries of the forthcoming station bulletins. The mailing lists are to be classified and henceforth only those publications of general interest will be sent to the entire list, except upon request. In this way it is hoped to lessen materially the expense of publication of results.

**Oregon College and Station.**—Plans are being drawn for the new dairy building which it is estimated will cost $30,000. The exterior will be of brick and stone and the floor of the first story of concrete. The milk, churning, refrigerator, separator, cream, cheese, and wash rooms, as well as the general offices, will be located on the first floor, and the milk-testing laboratory, class rooms, and shops on the second floor.

Recent additions to the station staff include F. C. Reimer, of the North Carolina College and Station, as superintendent of the Southern Oregon sub-station; R. H. Robinson as research assistant in chemistry; and L. R. Breithaupt as superintendent of the substation at Harney. F. L. Griffin, research assistant in plant pathology, has resigned.

**Rhode Island College and Station.**—The station has made an exhibit illustrating some of its work in agronomy and also in feeding ducks and in poultry diseases at the chamber of commerce exposition in Boston, which continued through the month of October. The college has shown some of the results of its school garden work in the same connection.

J. I. Falconer has resigned as assistant agronomist to engage in graduate study at the University of Wisconsin.

**Texas Station.**—David B. Clarkson, of Chicago, has donated $1,000 per annum to be used for cotton breeding and improvement work. It is hoped to supplement this with other funds and thereby to employ a cotton specialist for original research.

The position of agriculturist has been abolished, and H. L. McKnight, who formerly held the position, will be designated hereafter as superintendent of the station farm. A. B. Conner, of the Office of Forage Crops of this Department, has been appointed agronomist.

**Washington College and Station.**—Under a change in organization, effective October 1, R. Kent Beattie has been relieved of station work in order to devote his entire time to instruction. The department of botany of the station has been abolished, and a department of plant pathology created in its stead with
H. B. Humphrey, the plant pathologist of the station, as head of the new department.

**Wisconsin University and Station.**—The state legislature authorized a three-eighths of a mill tax for general university purposes. This tax will yield $1,089,000, of which the college of agriculture will receive for the ensuing year approximately $200,000. In addition to this, specific state appropriations for 1911 have been made of $40,000, an increase of $10,000 for agricultural extension, $4,500 for three demonstration farms, $2,000 for the maintenance of substations, $10,000 for the purchase of stump-pulling machines for experimental work, $10,000 for the soil survey, $75,000 for a home-economics building, $90,000 for an agricultural chemistry building, and $235,000 for 187 acres of land purchased by the university adjoining the university farm on the west, and to be used, so far as needed, for agricultural work.

W. D. Hoard, of Fort Atkinson, has resigned as regent. T. E. Brittingham of Madison, T. M. Hammond of Wauwatosa, and Elizabeth Waters of Fond du Lac, have succeeded Lucien S. Hanks, Frederick C. Thwaites, and D. P. Lamoreux as members of the board.

Appointment is made of a new course for public-health officials to be offered during the ensuing year. Applicants must hold a degree in medicine or sanitary science. The course extends through one year and leads to a diploma in public health. Special prominence is given to bacteriology and practical field work in the inspection of slaughterhouses, schools, factories, etc., but instruction is also given in physiology, zoology, meteorology, hydrology, public-health administration and vital statistics, and the microscopic examination of food and drugs.

F. H. King, widely known for his researches in soil physics and as the inventor of the King system of ventilation, died at his home in Madison, August 4, at the age of 63 years. Prof. King was educated at the State Normal School at Whitewater, Wis., and Cornell University. He began his long service in 1873 with the Wisconsin Geological Survey, and was professor of natural science in the River Falls State Normal School from 1878 to 1888. In the latter year he was appointed professor of agricultural physics in the University of Wisconsin, where in the ensuing 13 years much of his best-known work was done. In 1901 he carried on cooperative studies with this Office on the benefits of irrigation in Wisconsin. Soon afterwards he resigned to assume charge of the division of soil management of the Bureau of Soils of this Department. Upon relinquishing this position in 1904 he retired from public service, spending his remaining years largely in writing.

Among the many works from his pen are *The Economic Relations of Wisconsin Birds*, 1882; *The Soll*, 1895; *Principles of Agricultural Irrigation and Farm Drainage*, 1899; *The Physics of Agriculture*, 1900; and *Ventilation for Dwellings, Rural Schools, and Stables*, 1908. He had traveled extensively, and was completing at the time of his death a book entitled *Farms of Forty Centuries*, embodying an account of Chinese and Japanese farming as observed by him during a recent trip to the Orient.

**Wyoming University and Station.**—The *Wyoming Farm Bulletin* is being published monthly by the college and station staff in succession to the *Ranchman’s Reminder*. The general scope of the publication remains unchanged aside from the addition of a section for the answering of inquiries.

S. K. Loy, Ph. D. (Johns Hopkins University), has succeeded Dr. L. Charles Raiford as research chemist at the station, Dr. Raiford having accepted a position at the University of Chicago. Karl Steik has been appointed assistant chemist to study the effects of alkali on cement.
A grant of $3,100 has been made for remodeling the dairy barn.

**National Soil Fertility League.**—This organization has been recently formed, with headquarters at Chicago, for the purpose of bringing about more intensive cultivation of the soil. As a means to this end the provision of a local expert in each agricultural county, through state and federal aid to the agricultural colleges, is being advocated. Howard D. Gross, of Chicago, is president of the league and James J. Hill is chairman of the advisory committee, of which, among the members are President Taft, Secretary MacVeagh, of the Treasury Department; President E. J. James, of the University of Illinois; Hon. Champ Clark; ex-Governor W. D. Hoard, of Wisconsin; Henry Wallace, of *Wallace's Farmer*, and Hon. William Jennings Bryan.

**Fifth International Dairy Congress.**—The Fifth International Dairy Congress met at Stockholm, June 28 to July 1, with a large attendance and an interesting program. The sessions were held in the two chambers of the House of Parliament, two sections being formed, one discussing the production of milk and the other its handling and use.

In the first section the effect of foods upon the quality of milk and dairy products received much attention, especially from Messrs. Kellner, Böggild, and Hansson, as regards the effect on fat content. The final conclusions of the congress were in support of the theory that certain foods exercise an influence on the quantity of fat in milk in the case of cows having a high milk yield, but that further work is needed as to the conditions governing such an increase and as to its practical importance. Orla Jensen, of Copenhagen, reported negative results from a long series of experiments on the influence of fertilizers upon forage plants and the subsequent quality of milk and dairy products.

The congress indorsed the efforts of cow-testing associations for dairy improvement. The value of veterinary and other inspection of milk supplies was a subject of much discussion and a commission was appointed to suggest regulations applicable to such supervision.

The second section of the congress considered the questions of requirements to be exacted in milk and dairy products, analytical methods, cheese control, and the instruction of dairymen. A resolution was adopted strongly urging in all dairy publications the use of the metric system and of the centigrade thermometer scale.

Following the congress opportunity was afforded to visit the twenty-first General Swedish Agricultural Exhibit at Örebro, and other points of interest.

**Miscellaneous.**—Prof. Dr. J. König has retired as director of the agricultural experiment station at Münster, after 40 years' occupancy of the position, and has been succeeded by Prof. Dr. A. Börner, formerly vice director.

Dr. F. Bente, director for many years of the control station for fertilizers, feeding stuffs, foods, and seeds at Ebstorf, Prussia, died July 13.

Principles and practice of cider making, Barker ............................... 716
The principles of wine making, Bioletti .................................... 716
The significance of mineral salts in vinegar fermentation, Wüstenfeld .... 716
Paints; their service condition, Ladd and Ware ............................... 716

METEOROLOGY—WATER.

The Russian Bureau of Agricultural Meteorology, Broumov .................. 717
Changes in climate since the last glacial period .............................. 717
Monthly Weather Review .................................................. 717
Meteorological observations at Massachusetts Station, Ostrander and Hallowell. 717
Probable influence of the soil on local atmospheric radioactivity, Sanderson 718
Buckwheat and frost, Pulman ........................................... 718
Action of weather and moisture in soil on the growth of buckwheat, Pulman 718
Effect of weather on the growth of oats and millet, Pulman ................. 718
Action of soil moisture on the growth of oats, Pulman ....................... 719
The fertilizing value of rain and snow, Shutt ................................ 719
[Composition of rain water, British Guiana], Harrison ....................... 719
Further experiments on dew ponds, Martin .................................. 719
The geology of water supply, Woodward .................................... 719
The bacteriology of ice, Jordan .......................................... 719
Significance of flora and fauna in maintaining purity of natural waters, Marsson 719
Hypochlorite treatment of public water supplies, Johnson ..................... 720
Industrial sterilization of water with ultraviolet light, von Recklinghausen 720
Sewage pollution of Lake Erie and the Niagara River, McLaughlin ......... 720
Modern methods of sewage purification, Kershaw ............................. 720
Residential sewage disposal plants, Pratt ................................... 720

SOILS—FERTILIZERS.

Preliminary report on the Klamath marsh experiment farm, Scofield and Briggs 720
The conservation of [Iowa] soils ......................................... 721
A preliminary report on the mountain soils, Kilgore et al ................... 721
A chemical study of certain Sandhill soils of South Carolina, Keitt ....... 721
Analyses of characteristic northwest timber soils, Jones .................... 721
Soils of the Gezira, Beam .............................................. 722
The vineyard soils of Switzerland, Baragiola and Godet ..................... 722
The arsénil soils of Reichenstein, Silesia, Gruner ........................... 722
The weathering of silicate rocks, Stremme ................................ 722
Determination of the outer soil surface, Mitscherlich, Scheeffer, and Floess 723
The biological stimulation of natural humus, Remy and Rösing ............. 723
Examination of soils for organic constituents, Schreiner and Lathrop .... 723
The distribution of organic constituents in soils, Schreiner and Lathrop .... 724
A peculiar soil sickness, Hütig .......................................... 724
A comparison of soil disinfectants, Loew .................................. 724
Importance of fish in clay and granitic soils, Barcia y Trelles ............. 725
Potash in clay and granitic soils, Barcia y Trelles ............................ 725
Action of different proportions of lime and magnesia, Lemmermann et al .... 725
Investigations on the lime requirements of cultivated soils, Lemmermann et al. 725
The relation of recent soil investigations to the use of fertilizers, Cameron .... 725
The use of fertilizers from the time of Thaer to the present, Gerlah .......... 726
The use of commercial fertilizers on moors, heaths, and marshes, Tacke .... 726
CONTENTS.

Peach experiments 1906-1910, Garcia and Mundell.................................. 743
Experiments on processing persimmons to render them nonastringent, Gore........ 744
[Artificial ripening of dates]........................................ 745
The relation of handling to decay in California navel oranges, Stubenrauch.... 746
Report of the coffee expert, Van Leenhoff..................................... 746
The Department and importation of insect-infested or diseased plants, Wilson. 747

FORESTRY.

The prairies in Central North America and their value for forest culture, Baker 747
Management of Vermont forests with special reference to white pine, Hawes...... 747
Windbreaks: Their influence and value, Bates.................................. 748
National Forest Administrative Act......................................... 748
Forestry in Norway, Meyer.............................................. 748
Forest administration in United Provinces, 1909-10, Clutterbuck and Jackson. 748
A research on the pines of Australia, Baker and Smith......................... 748
Seeds and seedlings of the conifers, Hickel................................ 749
Grafting the chestnut on other Cupuliferæ, especially on the oak, Prunet.... 749
[Experimental tapings with rubber], McClelland................................ 749
The culture of Hevea.—The planters' manual, Cramer, trans. by De Wildeman. 749

DISEASES OF PLANTS.

Plant disease observations at Ultuna, 1910, Henning................................ 749
Fungi exotici: XII, Masee.................................................................. 749
On a new organ of the Mucorineæ, Guéguen...................................... 750
Some experiments with fungicides for stinking smut, Ditzell and Downing.... 750
On potato leaf blotch and leaf curl, Horne...................................... 750
Articles by the committee on the leaf-roll disease of the potato, Daferri...... 750
The leaf-roll disease.—II, The cause and propagation, Köck and Kornauth...... 750
The leaf-roll disease of the potato, Schander.................................... 751
American gooseberry mildew and black wart disease, Griffon and Maublanc. 751
The American gooseberry mildew, Salmon....................................... 751
New experiments on the control of the American gooseberry mildew, Wagner. 751
The weather and grape mildew in Hungary, De Istvanli and Savoly............ 751
Comparative experiments with certain sprays for downy mildew, Bretschneider. 751
Apple rust, Giddings.............................................................. 751
A canker of apple trees caused by the brown rot fungus, Salmon................ 752
Sooty blotch: A new fungus disease of apples, Salmon............................ 752
An uncommon disease of plum trees, Brooks.................................... 752
Peach freckle or black spot, Evans............................................. 752
A leaf spot of the olive and currucio on almonds and peaches, Ramos........ 752
Report of the pathologist, Fawcett............................................. 752
Report on the banana disease of Chinsurah, Basu................................ 753
Three fungus enemies of orange trees, Fawcett.................................. 753
The brown spot of the navel orange, Coit...................................... 753
Die-back fungus of Para rubber and cacao (Thyridaria tarda n. sp.), Bancroft. 753
The occurrence of burs on the trunk of Hevea brasiliensis, Bancroft........... 754
Nut diseases; with special reference to the pecan, Waite........................ 754
Notes on fungus diseases, PammeI............................................. 754
Zythia resinæ as an injurious timber fungus, Brick................................ 754
Blue stain on lumber, Rumbold................................................ 755
A disease of orchid leaves, Brooks............................................. 755
Extermination of eelworms, Smith............................................... 755
The chemistry of lime-sulphur wash, Burgess..................................... 755
Some recent experiments with lime-sulphur spray, Wallace....................... 755
Lime-sulphur washes for use on foliage, Salmon................................ 756

ECONOMIC ZOOLOGY—ENTOMOLOGY.

A biological survey of Colorado, Cary......................................... 756
The mammals of Bitterroot Valley, Mont., Henshaw and Birdseye................. 756
Threeimportant wild duck foods, McAtee...................................... 757
Officials concerned with the protection of birds and game, 1911, Palmer........ 757
Index-catalogue of medical and veterinary zoology, Stiles and Hassall......... 758
Report of the entomologist, Tower........................................... 758
The insect pest of the MoKameh Tal lands, Woodhouse and Dutt................. 758
Annual report of the entomologist for the year 1909-10, Anderson.............. 758
CONTENTS.

Insects in castor cake and stored grains in the central seed store. ........................................ 758
The Indian-meal moth and “weevil-cut” peanuts, Popenoe. .................................................. 758
Heat as a means of controlling mill insects, Dean. ..................................................................... 758
Citrus fruit insects, Quayle. .......................................................................................................... 759
Some important insect pests of the coniferce of the Himalaya, Stebbing. ................................. 760
Oviposition among tree crickets, Parrott. ....................................................................................... 760
Economic importance of Stictocephala, Osborn. .......................................................................... 761
The woody apple scale (Coccus pseudoponcatus), Greathouse. .................................................. 761
Macroaspis destructor and M. solanifoli, Patch. .......................................................................... 762
The rufous scale at Key West, Florida, Morrill ............................................................................ 762
Spraying for the euonymus scale, Metcalf. .................................................................................... 762
The San José scale and how to control it, Hayhurst. ................................................................. 763
Two important cantaloupe pests, Smith. ....................................................................................... 764
The apple-tree tent-caterpillar (Malacosoma americana), Conradi. ........................................ 764
Potato moth at Patna, Woodhouse and Chowdhuby. ............................................................... 765
Notes on the life history and habits of Pegomya brassicae, Schoene. .................................... 765
Oriental species of Stomoxys, Summers. ....................................................................................... 766
A fruit fly menace, Bremner. ......................................................................................................... 767
House flies, Howard. ..................................................................................................................... 767
The typhoid fly on the Minnesota Iron Range, Washburn. ..................................................... 767
Fleas on rats and readiness with which they bite man, Chick and Martin. ................................. 767
Life history of the rice weevil (Calandra orga) in Alabama, Hinds and Turner. .................... 768
The cotton square-weevil of Peru and its bearing on the boll weevil, Townsend. .................... 768
Bee keeping in Maryland. ............................................................................................................ 768
A method of securing the fertilization of clover by bumblebees, Washburn. .......................... 769
A new species of Cocophagus with the host relations of the genus, Howard. ................................. 769
The larch sawfly in Minnesota, Ruggles. .................................................................................... 770
A synonymic index-catalogue of spiders of America, Petrunkevitch. ........................................ 770
A handbook of the tsetse flies (genus Glossina), Asten. .............................................................. 770
Supplemental studies on trypanosomes, Kleine and Taute. ....................................................... 771
Spraying of woodland and shade trees, Worthley. ................................................................. 771
Spraying apparatus for scale insects, Worsham. ....................................................................... 772
The California insecticide law, Woodworth. ................................................................................. 772
Insect powder. ............................................................................................................................... 772

FOODS—HUMAN NUTRITION.

California white wheats, Shaw and Gurnitz. .............................................................................. 765
Wheat investigations—milling, baking, and chemical tests, Ladd and Bailey. ............................. 765
Milling experiments, Richardson and Stevens. ............................................................................ 766
Analysis of the products of hydrolysis of wheat gliadin, Osborne and Guest. ....................... 766
On the dietetic value of the so-called “standard” bread, Smetham. ........................................ 767
Bakers and baking in Massachusetts, Brayley. ............................................................................. 767
Rice as a foodstuff, Aron and Hocson. ....................................................................................... 767
Studies on chicken fat. ................................................................................................................. 767
Studies of cottage cheese, Windisch. ............................................................................................ 768
[The use of whale flesh as food], Andrews. .................................................................................... 768
Ptomaines in canned fish and crustacea, Desgrez and Catus. ....................................................... 768
Ripe and unripe bananas, Reich. .................................................................................................... 768
The composition of tomato catsups, Duckwall. ............................................................................ 769
Dirt in food, Dove. .......................................................................................................................... 769
Food chemistry and food control, Kraus. ....................................................................................... 769
Notices of judgment. ....................................................................................................................... 769
Special food analyses, 1911, Rose and Henry. ............................................................................. 769
[Food inspection and similar work], Winkler et al. ..................................................................... 769
The work of German institutions on examination of foods and condiments, 1907. ................ 769
[Living conditions in Samoa], Deeken. ....................................................................................... 770
The food of the Tasmanian aborigines, Noetling. ......................................................................... 770
Free restaurants for nursing mothers. ............................................................................................ 770
Household chemistry, Snell. ........................................................................................................... 770
Nutrition and growth, 1, Aron. ...................................................................................................... 770
Digestibility of white of egg as influenced by temperature, Frank. .............................................. 770
The metabolism of fruit acids in warm weather, Duckwall. ...................................................... 771
Colloidal-chemical analysis of phenomena of absorption and secretion, Fischer. ...................... 771
Muscular work and protein metabolism, Puglise. ........................................................................... 771
The human machine, Bennett. ....................................................................................................... 771
ANIMAL PRODUCTION.

The study of heredity, Haeccker ................................................................. 771
Introduction to the study of heredity, Baur ............................................. 771
An introduction to the science of heredity, Goldschmidt ................................................................. 771
A coefficient of individual prepotency for students of heredity, Harris ........ 771
On the formation of correlation and contingency tables, Harris .................. 771
Experimental polyspermny as a means of studying fecundation, Brachet ........... 771
Artificial parthenogenesis of frog’s eggs, Bataillon ..................................... 772
Chromosomes in Batrachians and in parthenogenetic embryos, Dehorne ........... 772
Effect of radium on the egg of the fowl, Vernoni .......................................... 772
The state of the ovary in hybrids of the goldfinch and canary, Chapellier ....... 772
On the cause of the fluctuations in growth of the fowl’s comb, Smith ............ 772
Castration by X-rays, Regaud and Nogier .................................................... 773
Sterilization by X-rays, Nogier and Regaud .................................................. 773
[Utilization of by-products of the vine as stock feeds], Vermorel and Dantony 773
Filling the silo and the cost of silage, Fugsley ............................................ 774
Concentrated feeding stuffs, Cathcart et al. .................................................. 774
Notice of judgment ......................................................................................... 774
The high price of meat in Germany: Its causes and remedy ......................... 774
Exports of Uruguay live-stock products, Goding ........................................... 774
Margarin in skim milk for fattening calves, Chiesi ....................................... 775
Breeding and feeding sheep, Wilson .............................................................. 775
The native breeds of swine in Croatia and Slavonia, Ulmansky ....................... 775
Cotton-seed meal feeding experiments with mules and horses, Curtis .......... 775
Feeding cotton-seed meal to draft animals, Curtis ......................................... 776
Method for determining weight of parts of eggs, Curtis ............................... 776
Illustrated album of pigeons, Schachtzabel ................................................... 777

DAIRY FARMING—DAIRYING.

Feeding experiments with cows and calves, Michels .................................... 777
Protein and total feed requirements for milch cows (abmelkkühe), Hansen .... 778
The “killing-out” system of dairying, Billingsley ......................................... 778
Dairy herd records, Shepperd and Richards ................................................. 778
The milk of some breeds of Indian cows, Meggitt and Mann .......................... 779
Progress of the dairy industry in Wisconsin, Taylor and Lee ....................... 779
The dairy industry in Hungary, Gorini ......................................................... 779
Dairy inspection in Bavaria, 1908–1910 ....................................................... 779
Report of the experiment station and school for dairying at Wreschen, Tiemann 779
Notices of judgment ....................................................................................... 779
The hygienic value of milk in Portugal, Pires de Lima ................................ 779
[Pasteurizing milk for children], Hanne ........................................................ 779
Pasteurizing of children’s milk, Neisser ....................................................... 779
Care of milk ..................................................................................................... 779
The importance of a certified or pasteurized butter, Hess ............................ 779
Yeasty flavored butter, Rosengren ............................................................... 780
Butter scoring contest for 1910, Davis ......................................................... 780
Experiments in making cheese with pure cultures, Gratz ............................. 780

VETERINARY MEDICINE.

Comparative microscopic anatomy of domesticated animals, Ellenberger ....... 780
In regard to the influence of bacterial toxins upon animal tissue, Vierhuff ... 780
The distribution of hemolysins, agglutinins, and poisons in fungi, Ford ...... 780
Leucoprotease and antileucoprotease, Bradley .............................................. 781
[Diseases of domestic animals in Mexico] ...................................................... 781
Report of the territorial veterinarian, Norgaard .......................................... 781
Proceedings under the diseases of animals acts, etc., 1910 ........................... 781
In regard to the diagnosis of anthrax with the precipitation method, Bierbaum 782
Endemic Malta fever with isolation of M. melitensis, Gentry and Ferenbaugh 782
Endemic Malta (Mediterranean) fever in Texas, Gentry and Ferenbaugh .... 782
[Endemic Malta (Mediterranean) fever in Texas], Gentry and Ferenbaugh .... 782
The intravenous injection of trypanblue in plasmosis, Henderson ............... 782
The transmission of Spirocheta duttoni, Hindle .......................................... 782
Sleeping sickness and trypanosomiasis, Thiroux and D’Ambrerville de la Salle 782
CONTENTS.

Strongyloides infections in man and animals in Isthmian Canal Zone, Darling... 783
Is lupus bovine tuberculosis? Engelbreth.................................................. 783
Infection of vertebrates by homogenous cultures of Koch’s bacillus, Arloing... 784
The detection of tubercle bacilli by the antiformin-ligroin method, Hall.... 784
Diagnostic and prognostic value of Russo’s reaction, von Szabóky.............. 784
Tests of various tuberculins when given internally, Pieifer and Leyacker... 784
Convenient table in the use of tuberculins, Kress..................................... 784
Anthrax and pirolusmosis in bovines, Galbusena........................................ 784
Actinomycosis in cows’ udders, Riddoch...................................................... 784
The action of Senecio alkaloids and causation of hepatic cirrhosis, Cushny... 784
Enzym and streptococci content of milk under asective conditions, Rullmann 785
Biology of hog erysipelas bacillus and two organisms similar, Schipp......... 785
Murrina, a trypanosomal disease of equines in Panama, Darling.................. 785
Mode of infection and methods used in controlling trypanosomiasis, Darling... 786
Investigations of Beschälsche, Zwick and Fischer....................................... 786
In regard to the treatment of equine influenza, Minder............................... 787
Etiology of canine distemper, Ferry............................................................ 787
Vaccinating with Piorkowski’s serum against canine distemper, Boden......... 787
Prophylaxis against echinococcus disease, Barabaschi............................ 787
A new species of cestode parasite (Tecnia balanieops) of dog and lynx, Hall... 787
Scabies of the rabbit, Jowett................................................................. 788
Tuberculosis in fowls..................................................................................... 788
The infective granule in certain protozoal infections, Balfour.................... 788
Feeding experiments in fowl spirochetosis, Balfour.................................. 788
Cecal parasites and rectal fauna of vertebrates, Martin and Robertson...... 789

RURAL ECONOMICS.

Urban and rural population of the United States........................................ 789
South’s marvelous agricultural progress...................................................... 789
Yearbook, 1910............................................................................................... 790
[Agriculture in Canada], Robertson et al..................................................... 790
Conservation of the soil, Taft................................................................. 790
The country-life movement, Bailey........................................................... 790
Bookkeeping for small farmers................................................................... 790
The Bavarian Central Loan Bank.................................................................. 790
Agricultural statistics of Bulgaria............................................................... 791
Agricultural statistics of Bengal for 1909–10............................................ 791
Foreign crops, August, 1911, Daugherty..................................................... 791
Legal weights (in pounds) per bushel of various commodities..................... 791

AGRICULTURAL EDUCATION.

Addresses and proceedings of the National Education Association, 1910......... 791
Opportunities for graduate study in agriculture in the United States, Monahan 792
[Agricultural and forestry education in Austria]........................................... 792
[Agricultural and forestry education in Austria]........................................... 792
Housekeeping instruction for girls in Prussia, Axt.................................... 793
Instruction in the practical agricultural schools, Barneda.......................... 793
Carrying the message to the people, Sparks.............................................. 793
Elementary school agriculture, Babcock and Stebbins.............................. 793
The school garden in the course of study, Babcock and Stebbins............... 793
Boys’ corn clubs and improved methods of corn growing, Bryant.............. 793
How to make an observation hive, Nickels.............................................. 794
University Farm School, Davis, Cal......................................................... 794
Announcement of farmers’ short courses for 1911..................................... 794

MISCELLANEOUS.

Thirty-third and Thirty-fourth Reports of Connecticut State Station, 1909–10.. 794
Twenty-third Annual Report of Louisiana Stations, 1910.......................... 794
Annual Report of Porto Rico Station, 1910................................................ 794
Monthly Bulletin of the Department Library, July, 1911............................ 794
Changes in inspection laws......................................................................... 794

</table>
The death of Hon. Norman J. Colman, first Secretary of Agriculture, calls to mind the beginnings of the American system of experiment stations and his services at that formative period.

Mr. Colman entered upon his duties as Commissioner of Agriculture on April 8, 1885. He came with the avowed conviction that the position was one of large importance and should be made a Cabinet office, that the Department's work should be strengthened, and that experiment stations for the benefit of agriculture should be established with Government aid in every State in the Union. The attainment of these and other ends for the advancement of agriculture and the recognition of its position he laid before President Cleveland as his program of action, in the interview preceding his appointment. That the latter looked with favor upon such a program is indicated by his selection of Mr. Colman out of a list of some thirty persons who were being considered for the commissionership.

When Mr. Colman came to the Department he found experiment stations in some ten or eleven States, working quite independently and without reference to one another, with no medium for exchange of views or agency for the promotion of their common interests, and no means except the press for giving wider publicity and application to their work. Most of them were small, struggling institutions with meager funds for maintenance, and several of them had no regular series of bulletins, but published their results only in newspapers or college catalogues or reports, where they were not widely accessible.

The development of the experiment station as an American institution remained to be worked out, and there was little or no united effort in that direction. The European station had been transplanted to a quite different environment, and around its successful adaptation centered many problems of organization, management, function and relationship, which needed to be worked out. This called for a closer union between the stations, an exchange of experience and views, and an extension of their interests beyond the boundaries of their respective States.
Commissioner Colman was convinced of this, as he tells us in his first report, and also of the great need of "a more practical cooperation between these institutions and the Department of Agriculture. . . . In a divided condition and without united purpose work will be often duplicated, experiments will be of local value only, and communities alone instead of States will have the benefit of the valuable results of science and practice."

One of his first administrative acts, therefore, only a month after taking office, was to call a meeting of delegates from the agricultural colleges and experiment stations, to be held at the Department, the first official gathering of the kind held in this country and the forerunner of the present Association of American Agricultural Colleges and Experiment Stations. In his call for this meeting he said: "The value of experiments in agriculture is due largely to the uniformity of methods by which they are made, and it is believed that by the comparison of methods which such a convention will permit, much can be done to simplify and unify the processes now in use. Much valuable time and a great deal of money are now lost in desultory and unmethodical experiments, which by concerted action among the various stations and colleges of the country, could be made productive of great good."

The proceedings of this first convention, held July 8 and 9, 1885, clearly show how fully Commissioner Colman was warranted in calling such a meeting and in his belief in the opportunity for more united action. The convention was attended by delegates from every section of the country, and the discussion covered a wide range of subjects and represented a variety of views. A stenographic report of its proceedings, now of much historic interest, was published by the Department.

Commissioner Colman delivered an opening address, in the course of which he presented forcefully and intelligently the need for experimental work in agriculture and the need of the farmer for "a knowledge of the laws—the definite and unvarying principles of physical science, as far as ascertainable," and he impressed upon the agricultural colleges their duty in this direction. "In my judgment," he said, "there is nothing which will attract and rivet the attention of the great agricultural public to our agricultural colleges so much as experimental work. Farmers will hope and expect to be benefited peculiarly by work of this character conducted at the agricultural college farms in their respective States."

Various measures had been suggested in Congress for establishing stations in connection with the land-grant colleges, and a measure known as the Cullen bill, similar in its general provisions to the Hatch Act, had been introduced. Among the first things which the convention did was to adopt a resolution setting forth "that the con-
dition and progress of American agriculture require national aid for investigation and experimentation in the several States and Territories; and that, therefore, this convention approves the principle and general provisions of what is known as the Cullen bill of the last Congress, and urges upon the next Congress the passage of this or a similar act.” So earnest was the convention in this matter that it appointed a committee on legislation, which was very effective in securing the passage of the amended bill.

The convention also expressed its approval of Commissioner Colman’s recommendation for a closer relation by adopting a resolution urging the creation of a branch in the Department of Agriculture which should be a special medium of intercommunication and exchange between the colleges and stations, and should publish a periodical bulletin of agricultural progress, containing in popular form the latest results in the progress of agricultural education, investigation, and experimentation in this and in other countries.

Commissioner Colman continued to lend his influence to the securing of Federal appropriation for experiment stations, and in his second report, in 1886, he heartily indorsed the plan for a national system of stations, with provision for cooperation and close communication with one another, and for publicity, so that the work of the stations would be made generally applicable and extended to the country as a whole. Referring to the proposed national legislation, he said: “Without interfering with the organization and management of the State stations, whether at colleges or independent, Federal support may supplement existing agencies and provide through this Department a certain degree of control to secure cooperation where needed and furnish such a medium of intercommunication and exchange as to greatly facilitate and improve the work as a whole.”

A bill providing for such a system and embodying these provisions had been introduced by Hon. William H. Hatch, of Missouri, Mr. Colman’s State, and referred to the Committee on Agriculture. This committee made a favorable report in March, 1886, and nearly a year later the bill was passed by Congress and was approved by President Cleveland.

Commissioner Colman was greatly gratified at the success of his efforts in establishing closer relations between the Department and the several colleges and experiment stations; and his views in regard to the value of a central agency, for promoting cooperation and intercourse and giving wider publicity to the station work, were embodied in the plans made soon after the passage of the Hatch Act, for the establishing of the Office of Experiment Stations. These plans included the issuing of a journal designated “Experiment Station Record,” which was begun in September, 1889, and a series of Farmers’ Bulletins to present the results of station work in popu-
lar form. The latter was the beginning of the present Department series.

In the organization of this new Office and the development of its plans for aiding the stations and making their work widely available, Commissioner Colman took a deep interest. It was a realization of a plan which he had early called attention to, and he felt that it was one of the important products of his administration.

It was through Commissioner Colman’s efforts, also, that the Division of Pomology and the Division of Ornithology and Mammalogy were established in the Department. The latter was in response to a demand for an investigation of the damage done to crops and fruits by birds, especially the English sparrow and the rice bird. Provision was also made for studies in vegetable pathology by the formation of a section in the Division of Botany; and in 1887 legislation and appropriations were secured which made the work of the Bureau of Animal Industry in the control of contagious diseases much more effective. As a result of this, the efforts of the Department in stamping out pleuropneumonia began to show good progress.

On February 9, 1889, the Department of Agriculture became one of the executive departments of the Government, and Commissioner Colman was appointed by the President the first Secretary of Agriculture, retiring with the close of the administration in the following month.

The period covered by Mr. Colman’s administration was one of relatively small things as measured by present-day standards. When he came to the Department its annual appropriation was less than $700,000, and at the close of his administration it received something over a million dollars. But it was a time of important change in the Department. It is noteworthy that he took a broad and advanced view for that time of what such an institution should be, recognizing the need of investigation as a basis for substantial advancement of the industry. This is exemplified in the way he took hold of the movement for experiment stations. He not only sympathized with this movement, but he gave it active support, and just how much his influence counted for in securing this legislation has not always been fully appreciated. When the measure had become a law he did not yield to the view that superficial practical work and the popular dissemination of information were the things to be largely encouraged, but he supported higher ideals for the new stations, and he appointed as his representative in the Department’s relations with the stations a man who stood for thorough scientific work in the acquisition of reliable agricultural knowledge, of which there had been but little in this country at that period.
We can see now that much depended on the holding up of these higher ideals and a right start at the beginning, and for this we owe much to the position taken by the first Secretary of Agriculture.

Mr. Colman was born at Richmond Springs, N. Y., May 16, 1827, and after studying law at Louisville, Ky., settled in St. Louis in 1852, where he had since resided. There he practiced law, and in 1865 established his agricultural paper, Colman's Rural World, which he continued to edit to the close of his life. He was the dean of agricultural editors in the United States, and was for many years a leader in agricultural movements and organizations in the Mississippi Valley. He was a member and former president of the State Board of Agriculture, a founder and first president of the Missouri Horticultural Society, the first president of the Missouri State Fair, and for fifteen years a trustee of the University of Missouri. He conducted a stock farm near St. Louis, and was actively interested in various other agricultural enterprises.

He had received honorary degrees from the Missouri and Illinois colleges of agriculture, and on his retirement from office in the Federal department he was decorated by the Republic of France, through its minister of agriculture, with the cross of "Officier du Merite Agricole."

Mr. Colman celebrated his eighty-fourth birthday last spring, and at that time was the recipient of many congratulations on his excellent health and vigor. He suffered a stroke of apoplexy on November 2, from which he died the following day.

The opportunities for graduate study in agriculture in the United States are presented in an instructive and convenient form in a recent bulletin issued by the United States Bureau of Education (noted on p. 792 of this issue). For the first time data as to the courses available for graduate instruction in agriculture and the related sciences have been gathered in a systematic way from the state colleges of agriculture and mechanic arts, the state universities, and the institutions represented in the Association of American Universities. These are classified by subjects and by institutions, anything like a direct comparison of institutions or attempt at standardization being avoided. The showing made is a gratifying one and brings out the remarkable progress which has been made in this direction within the past decade.

The bulletin is the result of a detailed inquiry undertaken by the Bureau of Education, in cooperation with the Association of American Agricultural Colleges and Experiment Stations, upon the initiative of its standing committee on graduate study. It represents much more than a mere compilation from college catalogues, being
rather a thorough study of the situation, in which such factors as
the equipment of the institutions to undertake real graduate work
and the qualifications of instructors have been given consideration.

Inasmuch as the purpose has been to restrict the inquiry to work
of strictly postgraduate grade, institutions with entrance require-
ments of less than fourteen units of high school work have been, with
two exceptions, excluded. Similarly, only courses limited to gradu-
ate students, and those undergraduate courses which may be taken by
graduate students as major subjects for advanced degrees, have been
listed.

Because of these limitations, only twenty-six institutions, of which
eighteen are land-grant institutions and four others State universities,
are included as meeting the requirements prescribed in the inquiry.
As a consequence, there have been omitted many other institutions
which offer work in agriculture to their own graduates and those of
other institutions whose degrees are equivalent. The bulletin states
that no fewer than forty-three of the land-grant colleges are now
offering graduate instruction of one type or another, and that "many
of the colleges whose courses are not included in this bulletin, owing
to their low entrance requirements, have excellent equipment and
facilities for research and investigation along a few special lines."

The graduate courses offered at the accepted institutions have been
classified under nineteen divisions of agricultural science. It is of
interest to note that of the twenty-six institutions, twelve present
courses in at least ten of these divisions, five in fifteen or more, and
two in seventeen branches.

It appears that botany is the most widely offered of the subjects
listed, twenty-two of the institutions offering courses. Of these, six-
teen give instruction in plant physiology, ten in plant pathology, and
nine in plant breeding. Bacteriology is offered by sixteen institu-
tions. Agricultural chemistry is also well represented, with courses
at nineteen institutions. Thirteen offer courses in soils and fertil-
izers, and a like number courses in physiology and physiological
chemistry.

Under the head of agronomy are listed sixteen institutions. Horti-
culture is offered by thirteen and forestry and landscape gardening
by seven each. Animal husbandry may be studied at fourteen of
the institutions and thirteen offer courses in animal nutrition. The
prospective student in dairying is restricted to nine institutions, in
zoology to thirteen, and in entomology to nine.

Despite the comparatively recent organization of instruction in
rural engineering and rural economics, these subjects have already
reached the graduate stage. Ten of the colleges have advanced
courses in rural economics and sociology, and six in agricultural en-
gineering, drainage, and irrigation. Advanced undergraduate work,
open to graduates, is available at 1 university in sugar technology and the wine industry, and courses of similar scope at another in theoretical and practical meteorology and climatology.

The data presented in this inquiry should prove of immediate service to the prospective graduate student, for whose needs the bulletin has been primarily prepared, and the publication will also find a wider application as an epitome of the present status of this important phase of agricultural education. Its usefulness received recognition at the recent convention of the Association of American Agricultural Colleges and Experiment Stations. That body formally expressed its appreciation of the work of the bureau in this connection, and urged the desirability of frequent revision of its records, and possibly the ultimate publication of another edition.

While perhaps not the least of the benefits which may be derived from such inquiries is in their suggestiveness as to the lines of study along which the opportunities are still inadequate, there is much reason for encouragement in the showing here presented. When it is recalled that so recently as 1902 the statement was made in these columns that "there has been comparatively little effort in our agricultural colleges in the direction of providing courses of postgraduate instruction in the different branches of agriculture," the advancement here revealed seems significant. The committee on graduate study of the association reported to the recent convention that on the basis of the inquiry it believed the extent of the opportunities now offered for graduate study of agriculture in the United States to be a source of gratification to all interested in the progress of agricultural education.

Now that this country has made a promising beginning in advanced training in agricultural subjects, it is only necessary that the training be recognized to insure further development of true university work in this field. In this connection the services rendered by the Graduate School of Agriculture, through its biennial summer sessions, deserve more active cooperation. As was pointed out by the committee, while the students of the graduate school have been enthusiastic in their commendation of this work, only about one person of every ten who might be expected to be interested has attended its sessions in any one year. In other words, only one out of ten of the total number of officers and assistants in the experiment stations, not including the instructors in agriculture not connected with the stations but to whom graduate study is equally important, has availed himself of its opportunities.

In commenting upon this the committee says: "After making all due allowances, this seems a very low percentage. Research is the lifeblood of the higher education, technical as well as liberal. If
the agricultural colleges confine themselves to teaching the things already known, either to their students in the classroom or to the farmer in the institutes and on the demonstration field, their success will be ephemeral. But research of the vital, fructifying kind demands training of a more advanced type than the undergraduate course can possibly give.” The committee expressed the conviction that the executive officers of colleges and stations should feel it incumbent upon them actively to encourage their graduates, and particularly those employed in the stations, to perfect themselves in their specialties. It suggested that each institution might well make systematic provision for the attendance of a portion of its force at each session of the graduate school, such attendance to be considered a part of their regular work and not a vacation.

In addition, more extensive and prolonged graduate study than is possible at the graduate school should be encouraged. This may be done, on the one hand, by leaves of absence on generous terms, and on the other by giving preference in appointment, other things being equal, to applicants who have had such training. It is believed that the widespread adoption of such a policy would do much to stimulate the cause of graduate study, and would give good returns in the development of more thoroughly trained men for agricultural research.
RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

A simplification in the methods for calculating analytical results, A. SCHOLZ (Chem. Ztg., 34 (1910), No. 121, pp. 1679, 1680).—After discussing the simplified methods for calculating phosphoric acid from magnesium pyrophosphate, the total dry substance in milk, and the copper from cupric oxid, the author describes methods for shortening the calculations for determining sugar and nitrogen in various products, and acetic acid in vinegar.

Determination of phosphoric acid in superphosphates and bone meal, Z. ROMÁNSKI (Chem. Ztg., 35 (1911), No. 18, pp. 163, 164; abs. in Jour. Soc. Chem. Indus., 30 (1911), No. 5, p. 237).—The work shows that if the precipitate obtained with magnesium mixture and ammonium citrate is washed with alcohol it will consist of 97 per cent of ammonium magnesium phosphate and 3 per cent of other matter, chiefly magnesium ammonium citrate, which makes such precipitates appear black after ignition and are only whitened with difficulty. In order to prevent such impurities the author recommends that the ammonium citrate and magnesium salt solution be acid in reaction, and to add these to the aqueous extract of the superphosphate under examination and slowly precipitate with ammonia. By doing this a crystalline precipitate of ammonium magnesium phosphate is obtained which is of uniform composition.

The preparation of the reagents and the detailed method of conducting the procedure are described. The results obtained by this method agree well with those obtained with Wagner's method.

A new procedure for determining sulphuric acid and sulphates, V. AUGER and M. GABILLON (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 8, pp. 441–443).—The method rests on the principle of reducing the sulphuric acid or sulphate with hydriodic acid, and determining the hydrogen sulphid formed by titration with iodin solution.

Biochemical classification of the proteins, E. HAUSER (Abs. in Chem. Ztg., 34 (1910), No. 35, pp. 843, 849).—This classification differs from the purely chemical one in so far that it considers the biogenetic relation of these bodies to metabolic processes.

On the refractive indices of solutions of certain proteins.—V. GLIDIN, T. B. ROBERTSON and J. E. GREAVES (Jour. Biol. Chem., 9 (1911), No. 3–4, pp. 181–184).—The value of a in the equation \( n = n_1 + a \times c \) where \( n \) is the refractive index of the solution of the protein, \( n_1 \) that of the solvent and \( c \) is the percentage concentration of the protein, has been determined for gliadin in various solvents.

In the less highly refractive solvents the introduction of gliadin increases the refractive index; but in the most highly refractive solvent employed, namely 75 per cent phenol, the addition of gliadin reduces the refractive index.

Fractional precipitation of milk proteins, A. J. J. VANDEVELDE (Biochem. Ztschr., 29 (1910), No. 6, pp. 461–464).—The author in a previous work has pointed out that certain transformations can occur between casein and albumin, and with another protein which occurs in colostrum. He furthermore expressed the opinion that casein and albumin were chemically not individual substances, and suggested a nomenclature, \( a \) for milk protein precipitated by an acid, \( \beta \) for that protein precipitated from the filtrate from \( a \) by the aid of heat, and a third mentioned as \( \gamma \).

---

In his present work he reports a new instance of this kind. In this he fractionated proteins \( \alpha \) and \( \beta \) with alcohol (methyl or ethyl) or acetone. He concludes that there are either 2 proteins present, 1 which can be transformed into the other, or that there is 1 present the nature of which is changed by irregular precipitation.

A method for the quantitative determination of aliphatic amino groups; some applications of this in the chemistry of the proteins, urine, and enzymes, D. D. Van Slyke ("Ber. Dcnt. Chem. Gesell.," 43 (1910), No. 14, pp. 3170-3181, fig. 1).—This method has been previously described in detail (E. S. R., 23, p. 303).

A method for quantitative determination of aliphatic amino groups, D. D. Van Slyke ("Jour. Biol. Chem.," 9 (1911), No. 3-4, pp. 185-204, fig. 1).—A portion of this work has been previously noted from another source (E. S. R., 23, p. 303).

The additional uses of the method are as follows: "Measurement of the velocity and extent of proteolysis, determination of the relative digestibility of proteins, quantitative determination of proteolytic enzymes, determination of the complexity and structure of peptides and proteolytic products," and for the "characterization of proteins."

Quantitative determination of prolin obtained by the ester method in protein hydrolysis; prolin content of casein, D. D. Van Slyke ("Jour. Biol. Chem.," 9 (1911), No. 3-4, pp. 205-207).—The prolin content of proteins can be rapidly and accurately ascertained by determining the total and amino nitrogen of the alcohol-soluble mixture. It was noted that each of the amino esters, the esters of which distill over with that of prolin, will give off all of its nitrogen when treated with nitrous acid as described in the Van Slyke method (E. S. R., 23, p. 303).

As a result of hydrolyzing 464 gm. of casein and esterfying according to the Fischer method the prolin nitrogen obtained was 3.775 gm., which corresponded to 31.1 gm. of prolin.

The results of attempts to crystallize out the prolin as a copper salt are also reported.

The carbohydrates of white pepper, K. H. Böddener and B. Tollens ("Jour. Landw.," 58 (1910), No. 3, pp. 220-231).—In order to investigate the substances from which furfural and methyl furfural (pentosans and methyl pentosans) originate, the authors conducted hydrolyzing tests with white pepper from which all substances soluble in alcohol (piperin, etc.) had been extracted. The sirup which was obtained by hydrolyzing the pepper for 6 hours with 5 per cent sulphuric acid and saturating the extract with calcium carbonate and purifying with alcohol only yielded with phenylhydrazin a phenyl-glucosan having a melting point of 203° C., and which originated from starch. Mannose-hydrazon was not obtained.

Attempts to remove the starch and its products with diastase and autoclaving and subsequent fermentation with yeast yielded negative results. As all the hydrolyzed solutions had an odor of furfural, and the vapor from such solutions reddened anilin acetate paper, the authors concluded that the pentoses were more or less decomposed by the preliminary treatment of the pepper. In order to determine this, they hydrolyzed and fermented another sample and examined the various intermediate products quantitatively for pentosans and methyl pentosans, with the following results: The extracted pepper before hydrolysis contained 2.21 per cent of pentosans and 1.73 per cent of methyl pentosans. The residue from the pepper after hydrolysis contained 0.29 per cent of pentosans and 0.05 per cent of methyl pentosans. The solution after hydrolysis, 1.79 per cent of pentosans and 1.05 per cent of methyl pentosans, the hydrolyzed solution after fermentation 1.04 per cent of pentosans and 0.33
per cent of methyl pentosans, and the sirup after treatment with alcohol 0.04 per cent of pentosans and 0.19 per cent of methyl pentosans.

A modification of the furfurol-hydrochloric acid method for estimating pentosans, K. H. Böddener and B. Tollens (Jour. Landw., 58 (1910), No. 3, pp. 232-237).—The authors present a modification of the Kröber method (E. S. R., 13, p. 320) for precipitating the furfurol in the distillate with phloroglucin at a temperature of from 80 to 85° C. instead of in the cold as is usual. The furfurol in this method quickly settles in the bottom of the flask as gray-blue-green flakes. The flask containing the distillate, after treatment with phloroglucin, is cooled for 14 hours and the residue collected on a Gooch crucible, where it is washed with 150 cc. of water and dried at from 95 to 98°. The residue is weighed in a glass-stoppered bottle.

In regard to the pentosans of some wood-destroying fungi, J. L. Wicbers and B. Tollens (Jour. Landw., 58 (1910), No. 3, pp. 238-242).—This work, while dealing with the pentosan content of various wood-destroying fungi, contains also a comparative study of the Kröber method (E. S. R., 13, p. 320) and the Böddener method (see above), and as the result of which the authors recommend the use of the Kröber method for general analytical purposes.

The results of the pentosan examinations were as follows:

### Pentosan content of several wood-destroying fungi.

In addition to pentosans, methyl pentosans were found to be present in these fungi. The results of a hydrolysis of *Fomes fomentarius* are also reported.

The determination of pentosans and methyl pentosans in cereals and fungi, M. Ishida and B. Tollens (Jour. Landw., 59 (1911), No. 1, pp. 59-67, fig. 1; abs. in Chem. Abs., 5 (1911), No. 15, pp. 2507, 2508).—The results for pentosans and methyl pentosans calculated to dry substance were as follows: "Corn 4.60 and 0.94 per cent, wheat 6.93 and 1.72, rye 8.41 and 1.69, barley 9.04 and 1.96, oats 12.39 and 1.52, *Polypora fomentarius* 2.58 and 1.74. *P. pinicola* 5.11 and 2.21. *P. hirsutus* 4.62 and 2.08. *P. fulvus* 4.10 and 1.01, *Daldara quercina* 3.05 and 1.17 per cent."

Pentosans in lower fungi, A. W. Dox and R. E. Neigh (Jour. Biol. Chem., 9 (1911), No. 3-4, pp. 267-269; abs. in Chem. Abs., 5 (1911), No. 15, p. 2588).—Six saprophytic molds, comprising the species *Aspergillus niger*, *A. fumigatus*, *A. clavatus*, *Penicillum chrysogenum*, *P. cambertii*, and *P. expansum*, were separated from a medium which consisted of cane sugar and inorganic salts, and the pentosan content of each determined. It varied between 0.86 and 1.17 per cent.

Fixing and staining tannin in plant tissues with nitrous ethers, A. E. Vinson (Bot. Gaz., 59 (1910), No. 3, pp. 222-224, figs. 3).—In connection with other work the author noted that the giant tannin cells contained in ripe dates and persimmons were darkened when stimulated to ripening by vapors of amyl and ethyl nitrite, and he points out that the above facts may be of value in studying the distribution of tannin in fruits.
"For laboratory use a 20 per cent alcoholic solution, made by diluting the 70 per cent commercial nitrous ether, is recommended. Amyl nitrite may be used, but is disagreeable to work with. Ordinary sweet spirits of niter, which contain about 4 per cent ethyl nitrite, may be used, but will require much longer exposure."

Botanical micro-chemistry, Grüss (Osterr. Chem. Ztg., 13 (1910), No. 23, pp. 289, 290).—This article deals particularly with the guaiac reaction, peroxidases, oxidases, oxygenases, diastases, and other plant substances which give the reaction for peroxidase, etc.

The artificial coloration of foods and condiments, E. Spaeth (Pharm. Zentralhalle, 51 (1910), Nos. 22, pp. 467-472; 23, pp. 495-501; 24, pp. 525-533; 25, pp. 557-566; 26, pp. 584-587; 27, pp. 614-618; 28, pp. 635-638; 41, pp. 935-948; 42, pp. 959-966; 43, pp. 987-991; 44, 1015-1018; 45, pp. 1037-1039; 46, pp. 1054-1058; 47, pp. 1076-1079; 48, pp. 1103-1106; 49, pp. 1122-1125).—This is an extensive and critical discussion in regard to the advisability and legality of the artificial coloring of foods, condiments, and beverages. The various colors employed and the methods used for detecting them are considered. The decisions of numerous courts are appended in each case.

Fruit juices and marmalades, E. Spaeth (Ztschr. Riech u. Geschmackst., 2 (1910), Nos. 1, pp. 155-157; 15-16, pp. 165-167).—This is a retrospect of the work done in regard to the judging and analysis of fruit juices and marmalades during the last few years. The more recent methods of analysis are described.

Composition of Tunisian olive oils, R. Marcille (Ann. Falsif., 3 (1910), No. 23, pp. 372-373; abs. in Jour. Soc. Chem. Indus., 29 (1910), No. 26, p. 1212).—This reports analyses of 550 samples of Tunis olive oils, representing all of the oils exported from the country from December 1, 1908, to March 31, 1910.

"The iodin values (Wijls) obtained were: Sfax oils 82.1 to 86.7, Sahel oils 81.2 to 84.5, Tunis oils 87 to 92.8. The liquid fatty acids separated from the oils had iodin values varying from 104 to 108. Certain of the oils from the Sfax and Sahel districts yielded color reactions similar to, but not identical with, those given by sesame oil; no less than 70 per cent of the oils from the Tunis district gave these reactions. The acidity of the oils was extremely low, 0.5 per cent of the total number of samples showing an acidity of less than 1 per cent."

See also a previous note (E. S. R., 22, p. 310).

Estimation of lecithin in oil, W. Fresenius and L. Grünhut (Ztschr. Analyst. Chem., 50 (1911), No. 2, pp. 90-106; abs. in Analyst, 36 (1911), No. 421, pp. 166, 167).—The method is as follows:

Fifty gm. of the fixed oil or fat is weighed in a 200 cc. graduated cylinder and agitated for 20 minutes with 100 cc. of absolute alcohol, allowed to stand for 1 hour, and the volume of alcohol and oil noted. Seventy-five cc. of the alcoholic solution is then pipetted off for the primary phosphorus determination. The pipette is washed out with absolute alcohol, and the washings added to the graduated cylinder, which is then filled up to the original mark with absolute alcohol. The shaking process is repeated, and after separation of the layers there has again taken place another 75 cc. of alcoholic solution is drawn off for a second phosphorus determination. The 2 alcoholic solutions, which are termed $a_1$ and $a_2$, are evaporated separately in a platinum dish and the dry residue fused with a mixture of sodium carbonate and nitrate. The phosphoric acid in the fused residue is precipitated with molybdic acid in the usual manner, ignited, dried, and weighed.

Two preparations of lecithin in oil were found to contain 3.11 and 7.8 per cent of lecithin, respectively.
Some further contributions in regard to the examination and judgment of milk, H. Lührig and L. Kressner (Molk. Zig. [Hildesheim], 25 (1911), No. 29, pp. 523-526).—Continuing previous work (E. S. R., 25, p. 207), the authors point out that hydrogen peroxid does not influence the refraction of a calcium chlorid milk serum, except that which follows the dilution by ordinary water and providing that the addition of this substance remains within certain limits (3 per cent H₂O₂). Lactic acid was found to alter the refraction of the serum in direct proportion to the amount added.

The authors were not able to agree with Mai and Rothenfusser, however, in regard to the undesirability of using spontaneously coagulated serums for determining the refraction. From some additional tests in regard to the relation of the specific gravity to the refraction of the spontaneous milk serum, they believe that just as good results can be obtained with such a serum as with the calcium chlorid serum.

The original acidity of milk, F. Bordas and F. Touplain (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 19, pp. 1274-1276; abs. in Chem. Zentbl., 1911, II, No. 1, p. 44; Ann. Falsis., 4 (1911), No. 32, pp. 297-301).—Milk reacts alkaline with bellanithin and lacmoid, while with phenolphthalein it reacts acid and with litmus amphoterically. The authors believe that the apparent acidity shown toward phenolphthalein is due to free casein. Milk, according to this, originally contains no free acid (lactic or citric) nor an acid salt. When fermentation of lactose sets in the acidity increases as a result of the separation of free casein from the calcium caseinate with the formation or monocalcium phosphate from the preexisting dicalcium phosphate. Lactic acid is only detectable with bellanithin when the reactions with the respective salts have taken place.

Determination of phosphorus in milk, C. Sloniewski (Bul. Soc. Chim. Belg., 25 (1911), No. 6, pp. 225, 226; abs. in Jour. Soc. Chem. Indus., 39 (1911), No. 14, p. 917).—As a result of determining the phosphoric acid in numerous samples of milk, the author finds that no appreciable loss of phosphoric acid takes place providing the incineration is conducted below a red heat. Preference, however, is given to the oxidation process, which uses nitric acid, owing to its simplicity and rapidity of execution. He believes that milk contains more phosphorus than the results already recorded show, and points out that there is apparently a constant ratio between the phosphoric acid and the ash, and not between the phosphoric acid and the proteins of the milk. Casein possibly does not contain any phosphoric acid at all.

The determination of phosphorus in milk, F. Bordas and F. Touplain (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 17, pp. 1127, 1128).—This is a reply to Fleurent and Lévi (E. S. R., 25, p. 411), in which the authors have controlled the results obtained by their method (E. S. R., 25, p. 312) which determines the phosphorus in the milk, serum, and coagulum. They do not believe that there is any loss of phosphorus by the action of carbon on the phosphates or the production of volatile phosphorus compounds with the fats.

The authors point out that the addition of foreign substances, such as falcum calcium and magnesium carbonate, barytes, etc., to the milk sample is not to be recommended.

The “neu-sal” milk test, J. Golding (Analyst, 36 (1911), No. 422, pp. 203-206).—The “neu-sal” method (E. S. R., 23, p. 614) is stated to give satisfactory results when the exact quantity of alcohol is used.

“The fact that it is not pure fat which is being measured, but a solution, the volume of which will vary with the quantity of alcohol used, makes the method inferior in accuracy to the acid Gerber method, a fault which is likely to be increased if it is put into the hands of inexperienced persons. On the
other hand, it is cheaper, safer, and more portable, and might be safely recommended to dairy farmers and others, to replace the acid method where this offers serious disadvantages; but the introduction of another possible error will prevent it from replacing the original Gerber method for more accurate work, though the method is a great advance on the previous alkaline methods."

Influence of various preservatives upon the results obtained with the "sal" method in the examination of milk and cream, Hesse (Milch Ztg., 39 (1910), No. 36, pp. 545, 555).—The results of a comparative study between the "sal" method and the Gerber method with milks preserved with formaldehyde, potassium bichromate, and copper ammonium sulphate are reported. The Gerber method was found to be influenced to a greater extent by the presence of preservatives in milk and cream than the "sal" method.

Determination of fat in butter by the "sal" method, M. Kersten (Molk. Ztg. [Hildesheim], 24 (1910), No. 18, pp. 311–313).—In order to determine the value of this method for butter in the hands of practical men, the author selected a number of students, etc., to try it out. The results obtained were compared with gravimetric determinations with the same material, and showed that the "sal" method, when conducted according to specifications and taking particular precaution not to shake the mixture, is a good accurate method.

Recent methods for examining butter for foreign fats, especially vegetable fats, C. Barthel (Svensk Kem. Tidskr., 22 (1910), No. 5, pp. 106–110).—A résumé of methods, with particular reference to the detection of coconut fat by means of the phytoestrin acetate method and the Polenske number.

The chemical processes involved in the fermentation of koumiss and kefir.—I, Investigations of koumiss in the Steppes, A. Ginzeberg (Biochem. Ztschr., 30 (1910), No. 1–2, pp. 1–24, digms. 3).—Inasmuch as there are various processes going on at the same time in the fermentation of koumiss and kefir, the author points out the impossibility of controlling the process by determining only the acidity. When utilizing various titration solutions such as tenth normal barium hydrate, tenth normal potassium hydrate, or a saturated solution of calcium hydrate, a disagreement among the final results was noted. The author, however, recommends diluting the koumiss with an equal amount of milk and then dividing it into 3 portions. Each of the 3 portions is allowed to ferment 6, 24, and 36 hours, respectively, and at the end of the fermentation period the total acidity, alcohol, and sugar are determined. A parallel biological examination is also made.

The flora most active in the fermentation of Katyk koumiss from mares' milk was found to consist of a long rod which often appeared in chains, simulated leptothrix, and an organism belonging to the true saccharomycetes or, possibly, to the torule.

The author further points out that the formation of peptones is not directly the result of a biological process, but is simply an ordinary hydrolysis of the proteins by acids.

As a result of making a parallel study of the decomposition of lactose and the formation of alcohol and lactic acid, it could be noted that at the beginning of the process only a slight production of alcohol took place, but it increased abruptly as soon as the yeast began to multiply and the sugar began to be decomposed. The lactic acid and alcohol formation became intense only when a certain equilibrium was established, and the competition between the yeast fungus and lactic acid bacterium became less.

The composition of koumiss and kefir is given and compared.
The chemical processes involved in the fermentation of koumiss and kefir.—II, Artificial koumiss and kefir, A. Ginzberg (Biochem. Ztschr., 30 (1910). No. 1–2, pp. 25–38, pl. 1, dmg. 1).—The koumiss utilized in this work was prepared with beer yeast for the production of the alcohol and Grigoroff's Bacillus bulgaricus for the production of lactic acid, etc., and with mares' and cows' milk. The kefir was prepared with kefir grains.

The work shows that the various processes in the kefir fermentation proceed much slower and less intensely than the koumiss fermentation, and that only 1 per cent of alcohol is produced and one-half of the quantity of the lactose is decomposed. With koumiss the alcohol content rises as high as from 2 to 3 per cent.

The author points out the advantage of establishing purely chemical limits which are based on the intensity of the fermentation process, and to eliminate such terms as weak (young and old), medium (young and old), and strong (young and old).

A number of practical hints on the preparation of koumiss and kefir are also given.

The determination of camphor, H. C. Fuller (U. S. Dept. Agr., Bur. Chem. Circ. 77, p. 1).—As camphor is extensively used in medicine, and the United States Pharmacopoeia contains preparations which must legally contain definite amounts of camphor, the author has elaborated a procedure for determining this substance. It is based on the fact that camphor forms with hydroxylamin a well-defined oxim (C₇H₉NO). Quantitative estimation of nitric acid in vegetable products, K. Kroog and J. Sebelen (Chem. Ztg., 35 (1911), No. 17, pp. 145, 116; abs. in Analyst, 36 (1911), No. 421, pp. 163, 164).—According to the authors Tiemann's modification of Schloesing's method, when used for determining nitric acid in vegetable products which contain much sugar (beets), yields inaccurate results owing to the reducing influence of the carbohydrates. While it is possible to remove the saccharose by precipitation as barium sucrate, the invert sugar which accompanies it can not be removed in this way.

In this connection the authors tested the value of Busch's nitron method (E. S. R., 36, p. 945) with aqueous and alcoholic extracts. The method gave with an alcoholic extract 1.65, and with the aqueous extract 1.63 per cent. Schloesing's and Tiemann's methods, on the other hand, yielded only 1.38 per cent. The authors have introduced certain modifications into the Busch method. Determination of malic acid, P. B. Dunbar and R. F. Bacon (U. S. Dept. Agr., Bur. Chem. Circ. 76, pp. 12).—A neutralized solution of malic acid when treated with uranyl acetate shows an increase in rotation which corresponds to approximately 28° Ventzke for each per cent of malic acid present in the solution. This principle is recommended by the authors for estimating malic acid quantitatively in substances free from d-tartaric acid, which is affected in the same way, by treating its solution with uranyl acetate, polarizing, and multiplying the difference obtained between this reading and a reading made of an untreated portion of the solution by 0.036. This represents the amount of malic acid present.

The most favorable limits of concentration for the method were found to lie between 0.2 and 2.5 per cent, and the percentage of error was never found to exceed 5 per cent of the malic acid present. The method, according to the authors, differs materially from the one previously noted (E. S. R., 24, p. 612), and with it 12 determinations can be made with ease in a few hours' time. If, however, more than 10 per cent of reducing sugars and less than 0.25 per cent
of malic acid are present, the uranyl acetate exerts its influence upon the sugars, and, therefore, when the approximate amount of sugar or malic acid is unknown some simple modifications must be made in the procedure. Numerous tests illustrating the above points, as well as some malic acid determinations in solutions (strawberry juice) containing an unknown amount of malic acid, accompany the description of the method.

Principles and practice of cider making, R. T. P. Barker (Jour. Inst. Brewing, 17 (1911), No. 5, pp. 425-441, figs. 2; abs. in Jour. Soc. Chem. Indus., 30 (1911), No. 11, pp. 915, 916).—Apples designed for cider production may be classified into a sour or sharp group. In which the malic acid content is above 0.45 per cent, a sweet class where the acidity is below 0.45 per cent and the tannin below 0.2 per cent, and a bitter-sweet group in which the malic acid is below 0.45 per cent but in which the tannin content is above 0.2 per cent. The kind of juice obtained from a certain apple is never constant and will always be found to differ with the seasons and the nature of the soil.

"Attempts to obtain a more regular type of fermentation by the use of selected yeasts have not led to very satisfactory results; this is not surprising in view of the variation in quality of the different juices due to the miscellaneous character of the raw material employed. It is quite possible that if a more or less standard quality of juice could always be used, fermentation with pure cultures would give more satisfactory results than natural fermentation. There are usually from 6 to 12 different kinds of yeasts naturally present in the juice; some are not numerous and are soon crowded out. During the earlier stages of fermentation, yeasts of the [Saccharomyces] apiculatus type appear to be most numerous, while ellipsoidus yeasts predominate at a later stage, and when the fermentation is finished and the cider has partly matured, a number of minute torula-like yeasts become conspicuous.

"Acetification is one of the most troublesome disorders of cider and roliness is also of common occurrence, but the most characteristic cider disease is that known as 'sickness.' This disease is very liable to appear in sweet ciders during May and June. At present there is no satisfactory method of preventing the disorder in cask, but the cider may be rendered less liable to sickness by blending the sweet type of juice with juices which normally ferment more rapidly, or by using a comparatively large proportion of apples of the sharp class, or by bottling the cider at a very much earlier date than usual."

The principles of wine making, F. T. Biolletti (California Sta. Bul. 213, pp. 335-443, figs. 4).—This bulletin discusses in detail the nature of wine, the biological theory of wine making, causes of variation in character and quality, the operations of wine making, the relation of micro-organisms, causes of fermentation, the micro-organisms found in grapes and wine, and the control of the micro-organisms before, during, and after fermentation.

The significance of mineral salts in vinegar fermentation, H. Wüstenfeld (Deut. Essigindus., 14 (1910), No. 38, pp. 275, 276).—A discussion in regard to the functions of various mineral salts in the vinegar fermentation process.

Paints; their service condition, E. F. Ladd and E. E. Ware (North Dakota Sta. Bul. 92, pp. 173-202, figs. 43).—"In compiling this report on conditions of test fences painted in 1906, 1907, 1908 and test houses painted in 1907, 1908, 1909, an endeavor has been made so to group the results as to bring together paints of similar type, thus to facilitate the comparison of such similar types under varying conditions, as well as to show the action of differing types under identical conditions of exposure." See also previous notes (E. S. R., 22, p. 710; 23, pp. 168, 371, 692; 25, p. 115).
The Russian Bureau of Agricultural Meteorology. Meteorological critical periods and crop growing. Agricultural forecasting, P. I. Bronov (Kratkii Ocherk Dicatel'nosti Meteorologicheskago Bluro za Verniu Ego Sushchestvovaniia. St. Petersburg, 1910; rev. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Int. and Plant Diseases, 1911, No. 4, pp. 794-796).—This bureau, which was organized in 1896, has accumulated a large amount of data bearing on the relation of meteorological factors to the life of cultivated plants and throwing light especially on the critical period of each plant. This work is prosecuted through a system of agricultural-meteorological stations established in 1907 throughout Russia in which the action of meteorological factors on the soil, growth of cultivated plants, and the life of domestic animals is studied. The first work of the bureau was published in 1908 and dealt with the action of meteorological factors on the growth in the chernozem, or 'black soils'” (E. S. R., 23, p. 117). Similar studies have been made with wheat, rye, millet, and corn. Another subject of investigation has been the effect of meteorological factors on the composition of cows' milk in Siberia. A system of forecasts based upon the color of the atmosphere has been successfully inaugurated.

The soils of Russia have been classified on the basis of studies of the action of climate on soils.

An atlas of agricultural meteorology and various other popular publications have been issued.

Changes in climate since the last glacial period (Die Veränderungen des Klimas seit dem Maximum der letzten Eiszeit. Stockholm, 1910, pp. LVIII+459, pls. 5, fig. 48).—This is a collection of articles presented at the eleventh International Geological Congress at Stockholm in 1910.

Monthly Weather Review (Mo. Weather Rev., 39 (1911), Nos. 4, pp. 487-648, charts 10; 5, pp. 619-814, figs. 6, charts 9, maps 2).—In addition to the usual climatological summaries, weather forecasts and warnings for April and May, 1911, river and flood observations, lists of additions to the Weather Bureau library and of recent papers on meteorology and seismology, a condensed climatological summary, and climatological tables and charts, these numbers contain the following special papers:

No. 4.—Forests and Floods, by J. W. Smith; Protection Against Frost, by E. W. Gruss; Frost in the Grand Valley and Colorado River Siphon, by F. H. Brandenburg; Variability of Frost Injury on Fruit Buds, by Philena F. Homer (see page 742); Measuring the Snow Layer in Maple Creek Canyon, by A. H. Thiessen and J. C. Alter; Notes on the Rivers of the Sacramento and San Joaquin Watersheds during the Month of April, 1911, by N. R. Taylor; Frost Fighting in California Vineyards, by W. E. Bonnett; Frost Cartridges, by A. G. McAdie; and biographical note on Jesse H. Robinson, 1843-1911.

No. 5.—Drought of 1910-1911 in South Carolina, by H. O. Geren; Tornado Near Howard City, Mich., by C. F. Schneider; Drenching the American Bottoms, by C. J. Root; An Excessive Downpour of Rain at Matagorda, Tex., by B. Bummemeyer; Where the Snow Lies in Summer (illus.), by J. C. Alter; Orchard Heating, by A. H. Thiessen (see page 743); Notes on the Rivers of the Sacramento and San Joaquin Watersheds during May, 1911, by N. R. Taylor; Protection against Frost—Frost Candles, by A. G. McAdie (see page 743); Fighting Frost, by J. E. Adamson; Correlation (illus.), by J. W. Smith; and The Trade Winds in Porto Rico, by O. L. Fassig.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. Ostrander and R. N. Hallowell (Massachusetts Sta.
EXPERIMENT STATION RECORD.

Met. Buls. 271, 272, pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during July and August, 1911, are presented. The data are briefly discussed in general notes on the weather of each month.

The probable influence of the soil on local atmospheric radioactivity, J. C. Sanderson (Amer. Jour. Sci., 4. ser., 32 (1911), No. 189, pp. 160-183, figs. 2).—This article reports and discusses the results of determinations of the amount of radium emanation in the underground air in the neighborhood of the Sloane Physical Laboratory of Yale University.

"It was found that 1 cubic centimeter of underground air contains radium emanation equal to the amount in equilibrium with 2.4X10^-13 gram of radium. This is equivalent to the production, per cubic centimeter of earth, of radium emanation in equilibrium with 8.9X10^-14 gram of radium.

"A method has been devised by which the amount of thorium emanation present in underground air can be directly measured in an electroscope and compared with the emanation evolved by a known weight of thorium salt. In this manner it was found that the earth in the neighborhood of the laboratory emits per cubic centimeter thorium emanation equivalent to that produced by 1.35X10^-5 gram of thorium under the standard conditions.

"The important bearing of the emanating power of the soil on the radioactive properties of the atmospheric air in different localities has been pointed out, and a method has been suggested by which the emanating power of the soil and the radioactive character of the underground air can be determined in any given locality."

Buckwheat and frost, I. A. Pulman (Ezheg. Dept. Zeml. [Russia], 1909, pp. 70, 71; Abs. in Internat. Inst. Agr. [Rome], Bull. Bur. Agr. Intel. and Plant Diseases, 1191, No. 4, p. 816).—It was found that —1 and —2 °C. did no harm to buckwheat seedlings, but at —2.5° the tenderest leaves began to suffer, at —4° nearly all the plants were damaged, and at —6° they were killed. The possibility of developing resistant varieties is discussed and a type developed at the Bogoroditsk station which resists a temperature of —4° is referred to.

Action of weather and moisture in soil on the the growth of buckwheat, I. A. Pulman (Ezheg. Dept. Zeml. [Russia], 1909, pp. 67-69; Abs. in Internat. Inst. Agr. [Rome], Bull. Bur. Agr. Intel. and Plant Diseases, 1191, No. 4, pp. 814, 815).—Experiments at the Bogoroditsk experiment station showed that there was a critical period in the life of buckwheat between flowering and the formation of grain. With sufficient rain at this period the yields were good. When conditions were favorable up to the period of flowering and then drought ensued there was a large production of straw but little grain. In the opposite case the yield of straw was less but that of grain higher.

In pot experiments it was shown that the maximum yield was obtained with a constant soil moisture content of 34 per cent from flowering to maturing of grain. A reduction of moisture from 34 to 24 per cent during the period from formation to maturity of grain reduced the yield, but an increase from 24 to 34 per cent during the same period gave a considerable increase of grain.

Effect of weather on the growth of oats and millet, I. A. Pulman (Ezheg. Dept. Zeml. [Russia], 1909, pp. 71-74; Abs. in Internat. Inst. Agr. [Rome], Bull. Bur. Agr. Intel. and Plant Diseases, 1191, No. 4, pp. 816, 817).—A study during 10 years of the relation of temperature, cloudiness, and rainfall to the growth of oats showed that "in years of good harvest, during the 10 days preceding formation of the ear there was abundant rain, rather low temperature, and a cloudy sky. In years of bad harvest, during the same period there was very little rain, the temperature was rather high, and the sky clear. Up to this period, whatever the outer conditions, the growth of the oats is uniform and
slow; but after the formation of the ears, up to harvest, they grow rapidly in favorable years. Rain is the most important factor, and the critical period is within the 10 days preceding the formation of the ears, generally in June."

Similar studies were made with millet, the results of which have already been noted from another source (E. S. R., 23, p. 117).

**Action of soil moisture on the growth of oats.** I. A. Pulman (Ezech. Dept. Zeml. [Russia], 1909, pp. 74, 75; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intl. and Plant Diseases, 1911, No. 4, p. 819).—Pot experiments at the Bogoroditsk experiment station showed that the optimum results were obtained with a constant soil moisture content of 34 per cent during the period from the appearance of the head to the setting of the grain, which is considered the critical period of oats; that a decrease in moisture from 34 to 24 per cent at this period decreased the yield 32 per cent; that an increase of moisture from 24 to 34 per cent during this period increased the average yield 11 per cent; and that the number of grains is larger but their size smaller with a constant soil moisture content during this period of 24 per cent.

The fertilizing value of rain and snow, F. T. Shutt (Ottawa Nat., 25 (1911), No. 6, pp. 99, 100).—In continuation of observations previously noted (E. S. R., 24, p. 417) it was found that the rainfall at the Ottawa Experimental Farm during the year ended February 28, 1911, was 19.67 in. and the snowfall 7.3 in., representing a total precipitation of 26.97 in., about 10 in. below the average for the locality. This precipitation furnished 5.271 lbs. of nitrogen per acre.

Of the average nitrogen (4.424 lbs. per acre) for the years 1908-1911, 84 per cent was supplied by the rain. Of the total nitrogen, 5.733 lbs. was in the form of ammonia.

[Composition of rain water, British Guiana], J. B. Harrison (Rpt. Expt. Agr. Work Dept. Sci. and Agr. [Britt. Guiana], 1909–10, pp. 15–18; abs. in Jour. Chem. Soc. [London], 100 (1911), No. 534, 11, pp. 530, 531).—The average annual rainfall at Georgetown. 1890 to 1900, was 99.27 in., furnishing 1.61 lbs. of nitrogen as ammonia, 1.89 lbs. of nitrate nitrogen, and 129.2 lbs. of chlorin per acre. Of the total nitrogen, therefore, 34.8 per cent was in the form of ammonia and 65.2 per cent in the form of nitrates.

Further experiments on dew ponds, E. A. Martin (Geogr. Jour., 36 (1910), No. 4, pp. 439–461, figs. 4).—In continuation of previous observations on this subject (E. S. R., 22, p. 118), the author reached a positive conclusion that "rain is undoubtedly the all-important replenisher of these, as of all ponds which are not fed by springs," and that dew plays an insignificant part in this process.

The geology of water supply, H. B. Woodward (London, 1910, pp. XII+339; rev. in Nature [London], 87 (1911), No. 2181, p. 206).—In this book an attempt is made to set forth clearly the main geological features to be taken into account by the engineer, chemist, or physical geographer in dealing with the problem of water supply, mainly in their application to conditions prevailing in the British Isles. A bibliography of the subject is appended.

The bacteriology of ice, E. O. Jordan (Cold Storage and Ice Trade Jour., 32 (1911), No. 1, pp. 31, 32).—Experimental data are summarized which lead to the conclusion that under suitable conditions freezing is a purification process and that any bacteria which remain in ice tend to disappear on storage. "Natural ice is habitually stored for a considerable period, and this fact materially increases its safety from the public health standpoint. After 3 or 4 months the danger from ice cut from even highly polluted water would be very slight, and after 6 months' storage would be practically negligible."

The significance of flora and fauna in maintaining the purity of natural waters, M. Marsson (Mitt. K. Prüfungsanst. Wasserrer, u. Abwässer, Berlin,
EXPERIMENT STATION RECORD.

1911, No. 14, pp. 1-26; rev. in Engin. News, 66 (1911), No. 9, pp. 246-250; abs. in Wasser u. Abwasser, 4 (1911), No. 9, pp. 377, 378).—This is a summary of information bearing upon the rôle played by the aquatic flora and fauna in maintaining the purity of streams and lakes and the effect of domestic sewage and industrial wastes upon such flora and fauna. A list of the scientific works of Dr. Marsson is appended to the article.

Hypochlorite treatment of public water supplies, G. A. Johnson (Jour. Amer. Pub. Health Assoc., 1 (1911), No. 8, pp. 563-574).—This article discusses briefly the adaptability and limitations of this process and to which extent it is actually employed in this country.

Industrial sterilization of water with ultraviolet light, M. von Recklinghausen (Elektrochem. Ztschr., 17 (1910), Nos. 8, pp. 211-216, figs. 3; 9, pp. 244-248, figs. 2).—The progress in the development of this method of water sterilization is briefly reviewed.

Sewage pollution of interstate and international waters with special reference to the spread of typhoid fever.—I, Lake Erie and the Niagara River, A. J. McLaughlin (Pub. Health and Mar. Hosp. Serv. U. S., Hyg. Lab., Bull. 77, pp. 169, charts 55, maps 16).—This bulletin discusses the relation of sewage polluted with water supplies to typhoid fever death rate with special reference to conditions along the New York, Pennsylvania, and Ohio shores of Lake Erie, and reports studies of these conditions, indicating a general dangerously contaminated condition of the lake waters drawn upon for the supply of the lake shore towns and cities and requiring purification works of high efficiency.

It is shown that this is a matter of great importance from the interstate and international standpoint, and it is maintained that “prevention or control of pollution of interstate and international waters should be a function of the Federal Government. The problem can not be handled by States, as uniformity of law and unanimity of opinion is difficult to obtain and almost too much to expect.”

Modern methods of sewage purification, G. B. Kershaw (London and Philadelphia, 1911, pp. XIII-356, pls. 36, figs. 15).—This book is intended as “a guide for the designing and maintenance of sewage purification works,” and deals with the following subjects: Conservancy methods, drainage areas, water supply, sewerage systems, rainfall, storm water, variations in flow of sewage, classification and composition of sewages, considerations to be observed in selecting the site for sewage disposal works, preliminary processes, disposal of sludge, land treatment of sewage, contact beds, percolating filters, trade wastes, and purification works in actual operation. Introductory chapters review the development of sewage purification during the last half century. One of the longest and most important chapters of this book deals rather fully with land treatment of sewage, the merits and limitations of this method being fully presented. The author holds that, with suitable land, moderate volume of sewage to be handled, and intelligent management, land treatment can not be excelled as a means of sewage purification.

Residential sewage disposal plants, R. W. Pratt (Mo. Bul. Ohio Bd. Health, 1 (1911), No. 7, pp. 228-235, figs. 4; abst. in Engin. and Contract., 36 (1911), No. 16, pp. 407, 408, figs. 4).—This article briefly discusses the general principles involved in the problem of disposing of sewage from individual houses, describing some of the simpler methods of sewage disposal.

SOILS—FERTILIZERS.

Preliminary report on the Klamath marsh experiment farm, C. S. Scofield and L. J. Burgs (U. S. Dept. Agr., Bur. Plant Indus., Circ. 86, pp. 10, fig. 1).—This circular reports the results of preliminary experiments to determine the
crop adaptation and the feasibility of leaching the Klamath marshlands, which include about 50,000 acres on the boundary line between Oregon and California.

It is stated that these lands have been formed from disintegrated aquatic vegetation without any considerable quantity of rock residue or silt, and contain injurious amounts of alkaline salts, chiefly sodium carbonate.

"On account of the highly impervious character of the marshland, the leaching out of these alkaline salts is rendered very difficult and appears to be impracticable by any methods at present known. The expense would exceed the prospective value of the land.

"The air-drainage conditions on the Klamath marshlands are such that low temperatures and killing frosts are likely to occur every month in the year, thus limiting the possible agriculture to the harder species of crop plants."

The conservation of [Iowa] soils (Rpt. Iowa Drain., Waterways and Conserv. Com., 1909-10, pp. 161-187, pls. 3).—This article discusses the causes of deterioration of soils, especially as applied to Iowa conditions, and urges the study of methods of conservation of their fertility.

A preliminary report on the mountain soils, B. W. Kilgore, E. L. Worthen and W. E. Hearn (Bul. N. C. Dept. Agr., 32 (1911), No. 5, pp. 52, figs. 9).—This bulletin reports the results of analyses of, and of fertilizer experiments on, the different soil types of the mountain section of North Carolina, and is based on 11 years' study of these soils to determine the different types, their location, extent, plant food and other constituents, fertilizer needs, and crop adaptation.

The soils are all residuary and are derived from igneous and metamorphic rocks, mainly gneisses, schists, and granites. The upland soils belong to the Porter's series, represented mainly by loam and sandy loam types, and smaller areas by clay, sand, and black loam. The valley and bottom lands are included in the Toxaway series and are of alluvial origin modified by colluvial wash. The two types thus far found are Toxaway loam and Toxaway fine sandy loam.

Although there is considerable variation, the soils as a whole are very high in potash, low in phosphoric acid, and fair in lime content. The amount of nitrogen varies with the quantity of vegetable or organic matter in the soil and is generally low. Fertilizer tests showed that potash did not benefit crops, but that phosphoric acid first, and nitrogen second, are the controlling constituents in increasing yields.

A chemical study of certain Sandhill soils of South Carolina, T. E. Keitt (South Carolina Sta. Bul. 159, pp. 3-24, fig. 1).—This bulletin reports the results of mechanical and chemical analyses of the Sandhill soils of South Carolina, and correlates these with past cultural and fertilizer practices on such soils, consideration being given to the distribution of plant food constituents.

The Sandhill region is situated below the fall line and comprises what was once the shore border. "It is believed to have been covered by the Lafayette formation, a very heterogeneous formation, composed of gravel, sand, silt, and clay, which ranges in color from brick red through various shades to white." In some places it has been eroded, and in others it has been covered by later and less gravelly marine formations. It embraces parts of Aiken, Lexington, Richland, Kershaw, and Chester counties.

Analyses of characteristic northwest timber soils, J. S. Jones (Jour. Indus. and Engin. Chem., 3 (1911), No. 4, pp. 246, 247).—This article reports the results of analyses of bench, valley, and elevated timber soils of Idaho.

The bench lands have an elevation of about 2,000 ft. The surface soil is a fine sandy loam, shading into a light clay loam at a depth of from 20 to 24 in., which continues to a depth of from 10 to 12 ft. without any material change in physical characteristics.
The valley lands are of alluvial formation, and of variable physical composition. Both the bench and valley lands are being developed for orchard purposes.

The elevated timber land has an elevation of from 2,500 to 3,000 ft., is covered with yellow pine and fir, and is of a rolling character. It is being converted into grain and timothy farms.

The analyses indicate clearly "that extensive areas of typical pine forest soils of the Northwest are well supplied with all of the mineral elements required in plant growth, and are exceptionally rich in phosphoric acid. As a rule, they are slightly acid in reaction, and, although substantial amounts of calcium are present, the application of finely crushed limestone is known to be of decided advantage in bringing them into a good state of cultivation."

Soils of the Gezira. W. Beam (Cairo Sci. Jour., 5 (1911), No. 58, pp. 181-189).—This article reports the results of chemical and mechanical analyses of soils from the Gezira, the triangular section of Sudan which lies between the White Nile and the Blue Nile.

In general the soils are fairly well supplied with potash and phosphoric acid but are markedly deficient in organic matter and nitrogen. The growing of legumes is, therefore, recommended for their improvement.

Contribution to the knowledge of the vineyard soils of Switzerland, N. J. Baracigola and C. Godet (Landw. Jahrb. Schweiz., 25 (1911), No. 3, pp. 213-224, fig. 1).—A preliminary test of the vineyard soils surrounding Wadenswyl, Switzerland, having shown a wide variation in their lime content, the authors made a more detailed study of these soils giving attention to mechanical and chemical analyses and the relation between the lime content of the soil and the parent rocks.

Among the more general conclusions it is stated that the soils which were richer in lime contained more suspended matter than sediment. The suspended portion of the soil was generally richer in lime than the sediment and the soils having the most sediment had the least retentive power for water.

The phosphoric acid content was generally somewhat higher in the surface than in the subsoil. The reverse was true of lime and magnesia, the magnesia content increasing practically in the same proportion as that of lime. A substantial part of the lime was present in a form other than that of the carbonate.

The rock particles contained a higher percentage of lime than the soil.

The arsenical soils of Reichenstein, Silesia, H. Gruner (Landw. Jahrb., 40 (1911), No. 3-4, pp. 517-557, pl. 1, fig. 1; abst. in Ztschr. Angew. Chem., 24 (1911), No. 41, p. 1976).—This article reports the results of studies to determine the origin of the arsenic in soils surrounding Reichenstein, Silesia.

It was found that the arsenic had come from the roasting furnaces, and that the parent rock did not contribute to its formation.

The sulphuric acid content of the soil increased with the arsenic, and it is thought that the harmful effects on vegetation and bee culture are in part due to the sulphuric acid, although the soils in the main showed a neutral reaction.

Lime was generally deficient in the soils and it is believed that applications of lime fertilizers would produce increased yields.

Some soils which contained large amounts of arsenic acid were also low in lime, phosphoric acid, and potash, and therefore from them, especially when coupled with such unfavorable physical conditions as generally existed, no profitable yields could be expected.

The weathering of silicate rocks, P. Stremme (Landw. Jahrb., 40 (1911), No. 1-2, pp. 325-338; abst. in Ztschr. Angew. Chem., 24 (1911), No. 25, p. 1187; Chem. Zentbl. 1911, I, Nos. 24, pp. 1714, 1715).—The author discusses the formation of kaolin on the basis of investigations by others and of his own experiments in which he tested the action of different acids on siliceous rocks.
It is shown that sulphuric, nitric, hydrochloric, and hydrofluoric acids decompose kaolin and, therefore, can not have contributed to its formation. Sulphuric and hydrochloric acids in the presence of little water form sulphates and chlorides. With large quantities of water and siliceous rocks they form almost pure silicie acid.

Tourmalin, fluor spar, topaz, and turquoise have nothing to do with the formation of kaolin, even though they are formed in unkaolinized rocks: fluorspar and boron are, therefore, not kaolinizing agents. Neither is hydrogen sulphid such an agent.

All analyses point to the fact that cold water containing carbonic acid is the principal kaolin-forming agent.

**Determination of the outer soil surface**, E. A. Mitscherlich, F. Schieffer, and R. Floess (Landw. Jahrb., 40 (1911), No. 5, pp. 645-659, fig. 1).—The authors report the results of studies of the hygroscopicity or outer surface area of a number of different soils as determined by Mitscherlich's method, previously described (E. S. R., 24, p. 419).

Although the authors admit that drying the soil produces colloidal changes, they believe that the establishment of vapor tension equilibrium by exposing the soil to 10 per cent sulphuric acid eliminates such colloidal changes or so reduces them as to render them negligible.

**The biological stimulation of natural humus**, T. Remy and G. Rösin (Centbl. Bakt. [etc.], 2. Abt., 30 (1911), No. 16-18, pp. 349-384; abs. in Jour. Chem. Soc. [London], 100 (1911), No. 386, II, p. 738).—This article reports a series of experiments which were undertaken to determine why the addition of soil to a mannite nutrient solution causes such a great development in the growth and nitrogen-fixing power of Azotobacter chroococcum.

The results, in agreement with those of Krzeminiowski, showed that the crude humus acid extracted from soil has an extraordinary influence in promoting the development and nitrogen-fixing power of A. chroococcum. It was found, however, that this effect was not due to the humus acids as such, but to the iron which the crude acids contained. Humus acids free from iron produced no such effect as the crude substances, whereas the addition of iron compounds alone to the mannite solution resulted in normal growth of Azotobacter and increased nitrogen fixation. One of the most effective forms of iron was found to be an alkaline solution of iron hydroxid in cane sugar. Iron silicate was also effective for this purpose.

**Examination of soils for organic constituents, especially dihydroxystearic acid**, O. Schreiner and E. C. Lathrop (U. S. Dept. Agr., Bur. Soils Bul. 80, pp. 33, pls. 2).—“This investigation is a partial survey of the nature of soil organic matter in the soils of the United States. Soils from 18 different States, extending from Maine to Oregon and southward to Texas, of widely different origin, topography, texture, climate, drainage, and cropping, varying from soils of the highest productivity to soils incapable of producing profitable crops, were examined for definite organic soil constituents.

“To facilitate this examination, the numerous individual methods for the separation of these compounds have been so coordinated as to form a single comprehensive procedure of analysis.

“In the soils so examined, pentosans, pentose sugars, histidin, cytosin, xanthin, hypoxanthin, and dihydroxy stearic acid were quite frequently encountered and the results indicate that these substances will be found to be widely distributed.

“Argenin, agroceric acid, lignoceric acid, a-monohydroxystearic acid, agrostol, phytosterol, and hentriacontane were only occasionally found, but no general statement as to their limited occurrence can be made.
"The frequent occurrence of dihydroxystearic acid is of special interest and significance because of its known harmful properties to plants. One-third of all the soils examined showed the presence of this compound. It was found in virgin soils as well as in soils under long cultivation; in soils continually cropped as well as in soils under permanent sod; in soils from the Atlantic coast; in soils from the Pacific coast; and in soils from the Gulf States. This compound is, therefore, a common soil constituent and is likely to be encountered in soils anywhere. Its formation or its accumulation is doubtless due to local conditions in any one section, but these local soil conditions are not confined to any region of the United States and probably not to any country or continent.

"When the soils examined are separated into good and poor soils, as based on field observations, their relationship with dihydroxystearic acid is rather striking. Among the good soils only 2 contained dihydroxystearic acid and they were of only moderate productivity. Among the poor soils the percentage of those containing this compound was 51. Of the soils which had a record for infertility, the dihydroxystearic acid was found in each and every case.

"Judging from the foregoing relationships established by this investigation it would seem that dihydroxystearic acid is either a direct or indirect factor in the low productivity in soils: direct by virtue of its harmful effects on growing crops, indirect as an indicator of other compounds or conditions which cause soil to become less productive and even infertile. It is not possible to state from the data at hand that dihydroxystearic acid is the only factor which contributes to the infertility or unproductivity in those soils in which it was found, for it must be remembered that this is only one of many compounds, both organic and inorganic, harmful and beneficial, which exist in soils, any and all of which play a part in its relative fertility and infertility. It is certain, however, that the determination of even this one constituent leads to a recognition of the kind of infertility in the soils examined and is, therefore, a readily recognized symptomatic factor of poor soil conditions."

The distribution of organic constituents in soils, O. Schreiner and E. C. Lathrop (Jour Franklin Inst., 172 (1911), No. 2, pp. 145-151).—This article is based upon results of investigations more fully reported above.

A peculiar soil sickness, J. Hudig (Landw. Jahrb., 40 (1911), No. 3-4, pp. 613-644, pl. 1; abs. in Ztschr. Angew. Chem., 24 (1911), No. 41, p. 1976).—Further investigations on the so-called "oat sickness" of the soils of Drenthe and Groningen (E. S. R., 21, p. 115) are reported, and deal with field and pot experiments to test the action of different fertilizers on such soils.

The sickness is not confined to moor soils, as was at first supposed, but occurs also on sandy and clay soils. Although the investigation is not complete, the author believes that the sickness is due to changes in the composition of the humus caused by continued application of lime and physiologically alkaline fertilizers.

A comparison of soil disinfectants, O. Loew (Porto Rico Sta. Rpt. 1910, pp. 17-19).—Comparative tests of chlorid of lime, potassium permanganate, trichresol, and carbon bisulphid on "sick" soil planted to lilies are reported. The largest production of flowers and seed was obtained on the plat treated with chlorid of lime, which is considered the best and cheapest of the soil disinfectants tested.

Importance of soil reaction in relation to soil investigations and productivity, M. Weibull (Meddel. Almarps Lab., 1911, No. 12, pp. 32).—This article reports studies of the extent to which the solubility of the plant food in the soil, the effect of fertilizers, and the yield of crops, depend upon the reaction of the soil.
The results of both analysis and vegetative experiments agreed in showing that acid soils contained smaller amounts of available nitrogen and phosphoric acid and usually lower percentages of potash than neutral or alkaline soils. As a rule, also, yields were lowest on acid soils and highest on neutral and alkaline soils.

**Potash in clay and granitic soils,** J. Barcia x Trelles (*Prog. Agr. y Pecuaria, 17* (1911), Nos. 727, pp. 349–351; 728, pp. 365, 366; 729, pp. 382, 383).—This article emphasizes the fact that, although determinations of potash may in some cases furnish valuable indications of the potash requirements of soils, analysis is not an infallible guide and should be supplemented by field experiments. It is shown that many soils derived from granites and rich in potash are benefited by potash fertilizers.

**Investigations on the action of different proportions of lime and magnesia in some soils on higher plants and micro-organisms,** O. Lemmermann, A. Einecke, and H. Fischer (*Landw. Jahrb., 40* (1911), No. 1–2, pp. 173–254; *abs. in Chem. Zeitbl., 1911, 1, No. 25, pp. 1769, 1761; Ztschr. Angew. Chem., 24* (1911), No. 25, pp. 1187, 1188; *Jour. Soc. Chem. Indus., 30* (1911), No. 13, p. 821; *Chem. Abs., 5* (1911), No. 13, p. 3314).—The authors report the results of a large number of experiments conducted during 1907, 1908, and 1909 on 6 soil types and with 8 different crops, to determine the action of different proportions of lime and magnesia on plants and soil organisms (bacteria).

It was found that as far as the yield was concerned variations within wide limits in the proportion of lime to magnesia had no effect. It was not possible to increase the yields by maintaining definite proportions of lime to magnesia.

Plants varied in their behavior toward lime and magnesia. Even soils containing only 0.08 per cent lime and 0.04 per cent magnesia, or 0.067 per cent lime and 0.09 per cent magnesia, gave no increase in yield with many plants from applications of lime and magnesia. It seems necessary, therefore, that in order to draw correct conclusions the same plants must be studied for several consecutive years on the same soil.

The favorable action of lime on the mustard plant was not dependent alone upon the nutritive value of lime, but also upon other factors.

The lime content of grain was much less than that of straw. Grain and straw varied less in magnesia than in lime. Grain contained more magnesia than lime, whereas the straw contained more lime than magnesia.

Variable amounts of lime and magnesia applied to, as well as contained in, the soil influenced more distinctly the composition of the straw than that of the grain.

The lime, magnesia, and phosphoric acid content of plants may vary greatly for substantially the same yields.

The lime-magnesia fertilizers influenced also the utilization of phosphoric acid in that a high magnesia and a low lime content of fertilizer decreased the lime content of the crop, whereas that of the phosphoric acid and magnesia increased.

The varying solubility and absorption of lime and magnesia fertilizers must be considered in the determination of the exact relation of lime and magnesia in the soil.

As with the higher plants, no distinct relation of lime to magnesia could be established as particularly favorable to soil bacteria.

The authors believe that the study of the optimum proportion of all plant nutrients to each other is an important work of the future.

**Investigations on the lime requirements of cultivated soils,** O. Lemmermann, O. Foerstler, and A. Einecke (*Landw. Jahrb., 40* (1911), No. 1–2, pp. 14867.—No. 8–11—3
EXPERIMENT STATION RECORD.

255-324; abs. in Chem. Zentrbl., 1911, 1, No. 25, pp. 1761-1763; Ztschr. Angew. Chem., 24 (1911), No. 25, p. 1188; Jour. Soc. Chem. Indus., 30 (1911), No. 13, p. 821; Chem. Abs., 5 (1911), No. 19, p. 3371).—This article reports the results of tests of different methods of determining lime in soils, and correlates these with results of a large number of pot experiments with lime fertilizers conducted during 1905 and 1906 on 10 soil types and with a number of different plants.

It was found that the usual methods of determining lime in soils gave uncertain results, but that the authors' simplified method, extraction with 10 per cent hydrochloric acid, was more satisfactory. The lime content as determined by this method, however, gave no reliable indication of the behavior of the soil toward a lime fertilizer. The lime content obtained by extraction with 10 per cent hydrochloric acid was substantially the same as that from extraction with ammonium chloride, lower than that for the sulphuric acid extraction, and higher than that for the carbon dioxide solution.

Different plants varied in their behavior toward lime fertilizers and the acidity of the soil. The utilization of the lime of the fertilizer, as well as of the soil, was small, the highest amount being about 4 per cent for the soil and about 5.6 per cent for the fertilizer. There was no relation between the lime taken up by the plants on different soils, and that which was soluble in carbon dioxide solution. There was no constant relation between the lime assimilated by the plants and that soluble in a soil solution.

The authors are of the opinion that mineral soils are more generally acid than is commonly believed, and that the determination of the acid content of soils must be given more attention in the future.

The relation of recent soil investigations to the use of fertilizers, F. K. Cameron (Amer. Fert., 35 (1911), No. 3, pp. 52-56).—This article is in large part a review of soil investigations and a statement of the teachings of the Bureau of Soils of this Department with reference to soil fertility. It discusses the composition and individuality of soils, dynamic properties, natural supply of mineral nutrients, organic constituents, soil management, and the use of fertilizers.

The development of the use of fertilizers from the time of Thaer to the present, Gerlach (Jahrb. Deut. Landw. Gesell., 26 (1911), No. 1, pp. 145-154).—A historical review for Germany.

The use of commercial fertilizers on moors, heaths, and marshes, Tacke (Jahrb. Deut. Landw. Gesell., 26 (1911), No. 1, pp. 137-144).—A brief review of present knowledge on this subject.

Drill manuring in Hungary, J. Győrffy (Deut. Landw. Presse, 38 (1911), No. 17, pp. 193, 194; abs. in Internat. Inst. Agr. [Rome], Bull. Agr. Intal. and Plant Diseases, 2 (1911), No. 4, pp. 824, 825).—In experiments with barley, oats, rye, and wheat here reported 115 kg. of superphosphate per hectare (102.35 lbs. per acre) applied with a drill gave better results than 345 kg. (307.05 lbs.) applied broadcast.

The loss of ammonia from manured soils, P. Ehrenberg (Fühlings Landw. Ztg., 60 (1911), Nos. 13, pp. 141-152; 14, pp. 479-500).—Investigations on this subject are reviewed, showing that when manure is incorporated with the soil there is practically no loss of ammonia but that a considerable loss occurs under certain conditions when the manure is spread on the surface of the soil.

The production of ammonia from peat, N. Caro (Chem. Ztg., 35 (1911), Nos. 56, pp. 505-507; 57, pp. 515, 516).—Investigations on the production of ammonia from wet and dry peat by treatment with steam under pressure are reported, showing that the production is larger and more rapid from wet peat and that there is no fixation of atmospheric nitrogen in the process.
Manuring experiments with peat. A. I. Dreiman (Zemledel’stvo, 1910, No. 3; abs. in Zhum. Opinia. Agron. (Russ. Jour. Expt. Landw.), 11 (1910), No. 6, pp. 867, 868; Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intern. and Plant Diseases, 2 (1911), No. 3, pp. 527, 528).—In experiments with peat alone and in combination with bone ash, Thomas slag, potash salts, and sodium nitrate on barley grown on sandy soils, it was found that peat alone nearly doubled the yield of grain but that peat mixed with Thomas slag, potash salts, and sodium nitrate did not give as large a yield as a complete mineral fertilizer without peat.

The hygroscopicity of certain new nitrogenous fertilizers, H. von Feilitzen and I. Lugner (Fühling’s Landw. Ztg., 60 (1911), No. 16, pp. 563–568, duym. 2).—In comparative tests of samples of Norwegian nitrate and lime nitrogen mixtures, equal parts of the two, and of 2 of lime nitrogen to 1 of Norwegian nitrate, ammonium sulphate, and sodium nitrate, it was found that all of the substances gained considerable moisture in a period of one month, the most hygroscopic being the mixture of 2 parts of lime nitrogen to 1 of Norwegian nitrate, the least hygroscopic lime nitrogen. The Norwegian nitrate and lime nitrogen and both mixtures of the two gained in weight in dry air, the 2:1 mixture showing the largest gain.

Some fertilizer experiments with different potash minerals, H. von Feilitzen (Dent. Landw. Presse, 38 (1911), No. 63, pp. 737, 738, fig. 1).—The author reports the results of pot and field experiments conducted during 1910 with barley and field peas on moor soils to determine the relative action of phonolite, nephelite, feldspar, and a so-called powdered “aluminate” as compared with the 38 per cent Stassfurt potash salt.

He concludes that although phonolite and nephelite gave an appreciable action, they were far inferior to the Stassfurt salt both in point of yield and potash assimilation. Feldspar and the powdered “aluminate” gave such inferior yields as to merit no consideration.

A new mineral yielding potassium sulphate (Engrais, 26 (1911), No. 10, p. 272; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intern. and Plant Diseases, 2 (1911), No. 3, p. 535).—Attention is called to the discovery in the Province of Almeria, Spain, of a mineral which by calcination and washing yields from 25 to 30 per cent of potassium sulphate. It is called “Galafatite.”

The German potash industry, T. J. Albert (Daily Cons. and Trade Rpts. [U. S.], 14 (1911), No. 172, p. 377; Engin. and Min. Jour., 92 (1911), No. 6, p. 252).—It is stated that “at the conference held recently at Hamburg between the conflicting interests, German and American, in the potassium industry, an agreement has been reached as to prices and rebates. The agreement has a duration of 5 years. During this period the American purchasers of potash obligate themselves to make all purchases from the potassium syndicate. The probability of the market being disturbed by outside mines is thought to be remote, as such outsiders would have to organize a sales agency in the United States similar to the German Kali Syndicate, which delivers potash salts directly to the buyer. Such an organization would be expensive and difficult to effect.

“The basis of prices is practically the same for concentrated salts as that contained in the potassium law, and the same as prevailed in America in 1909 before the syndicate was renewed and before the Schmidtman contracts went into force.”

Potash residues as manure, L. Sapartovitch (Khozvzoistvo, 6 (1911), No. 3, pp. 69–71; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intern. and Plant Diseases, 2 (1911), No. 3, pp. 534, 535).—This article gives analyses and discusses the fertilizing value of leached wood ashes obtained as residues from
the preparation of potash. It is shown that these residues sometimes contain as high as 1 per cent of potash, 1½ per cent of phosphoric acid, and a relatively large percentage (over 20 per cent) of lime. They are, therefore, of considerable fertilizing value, particularly on soils benefited by lime.

The best method of applying lime to arable land, R. P. Wright (West of Scotland Agr. Col. Bul. 55, pp. 197-216; abs. in Mark Lane Express, 105 (1911), No. 4496, p. 345).—In comparative tests of different rates and times of application of burnt lime and of the use of gas lime on cereals, fruit crops, and hay, it was found that in the case of medium and light soils large applications of not less than 4 tons per acre at long intervals of time were much less effective than the same amount of lime applied in divided applications at shorter intervals. Gas lime applied at the rate of 4 tons per acre for turnips produced a much smaller increase than an equal amount of burnt lime, but in the 7 succeeding years of rotation its action was much more beneficial to crops. "In that period it gave a total increase of more than 3 times the value of that produced by burnt lime, and on account of its low cost and its efficacy it gave much more profitable returns than any other lime dressing used in the experiment."

Relative economy of ground and slaked limes, R. P. Wright (West of Scotland Agr. Col. Bul. 55, pp. 219-221; abs. in Mark Lane Express, 105 (1911), No. 4496, pp. 217-221).—The general conclusion from the experiments here briefly reported is that properly slaked lime can be as uniformly and completely distributed as ground lime and is more effective.

Lime for agricultural purposes, A. J. Patten and J. A. Jeffery (Mich. Sta. Circ. 11, pp. 79-82).—This is a brief popular compilation of information on this subject.

Experiments with sodium chlorid as a fertilizer for sugar beets, F. Strommer and O. Fallada (Österr. Ungar. Ztschr. Zuckerindus. u. Landw., 40 (1911), No. 3, pp. 425-441).—The experiments here reported dealt particularly with the use of a mixture of ammonium sulphate and sodium chlorid as a substitute for sodium nitrate, and showed that such a mixture is fully as effective as regards yield and sugar content of beets as nitrate of soda, and that the sodium base left in the soil by the sodium chlorid fertilizer does not behave differently from that resulting from the assimilation of sodium nitrate. The results therefore indicate that the sodium-chlorid-ammonium-sulphate mixture may profitably replace sodium nitrate under certain conditions.

The article contains a short bibliography of the literature bearing upon the subject.

The influence of molasses on soil fertility (Agr. News [Barbados], 9 (1919), No. 222, p. 339; 10 (1911), No. 238, p. 179; abs. in Internat. Inst. Agr. [Rome], Bul. Rev. Agr. Intl. and Plant Diseases, 1910, No. 2, pp. 230, 231).—This article briefly summarizes the results of experiments in Mauritius (E. S. R., 21, p. 724), Antigua, and Hawaii (E. S. R., 24, p. 224), with molasses as a fertilizer for sugar cane, indicating "that the application of molasses to fallow land, or to land in which sugar cane is to be planted after several weeks have elapsed, may have a beneficial effect in stimulating the action of the nitrogen-fixing organisms and thus adding to the store of nitrogen for the crop that will be growing after such a time has elapsed as will have allowed this stimulus to have had its proper effect."

The beneficial effect observed may also be due in part to the relatively large percentage of potash present in the molasses.

It was shown in the Hawaiian experiments "that molasses applied at intervals to growing canes which have received artificial manure is likely to do harm, either by destroying nitrates that have been already applied or by
AGRICULTURAL BOTANY.

preventing nitrates from being formed from other compounds containing nitrogen, in the manure."

In the Antigua experiments the application of 400 gal. of molasses per acre increased the yield of cane 1.2 tons per acre. The application of 200 gal. of molasses per acre did not increase the yield.

The agricultural utilization of certain waste products, T. Griffet (Journ. Agr. Prat., n. ser., 32 (1911). No. 33, pp. 200–202; Engrais, 26 (1911), No. 31, pp. 93–95).—This article gives the principal fertilizing constituents and discusses the price of various animal and vegetable waste products such as meat, bones, hair, wool, poultry manure, pondreut, peanut oil cake, silkworm chrysalis, sardine waste, tobacco waste and ash, calcium carbide waste, and wastes from wine, sugar, and oil making.

Commercial fertilizers, M. A. Scovell and H. E. Curtis (Kentucky Sta. Bul., 152, pp. 193–322).—This bulletin reports the analyses and valuations of 555 brands of fertilizers inspected by the station during the year 1910.

Fertilizer inspection (Maine Sta. Off. Insp. 33, pp. 77–108).—This circular reports the analyses of samples of fertilizers found on sale in Maine in 1911 with notes on the requirements of the state law and the nature and use of fertilizers.

AGRICULTURAL BOTANY.

Studies on fruit respiration, H. C. Gore (U. S. Dept. Agr., Bur. Chem. Bul., 142, pp. 49, figs. 3, dagrams. 1½).—This bulletin gives the results of experiments on the effect of temperature on the respiration of fruits, the effect of picking on the rate of evolution of carbon dioxide by peaches, and the rate of accumulation of heat in the respiration of fruits under adiabatic conditions. An absorption apparatus and a constant temperature incubator suitable for use in the study of the respiration of fruits are described.

Measurements are given of the rate of respiration at different temperatures of many fruits, such as berries, peaches, apples, grapes, etc. The respiration intensity of these fruits varied greatly, but when the data were plotted similarly shaped curves were formed.

No correlation between composition or size and respiratory activity appeared. In general, however, fruits which grow and mature quickly and soon become overripe respire rapidly. This is true of most small fruits. On the other hand, fruits with a long growing period and maturing slowly, such as the citrus fruits, are very inactive physiologically. Peaches, plums, apples, pears, and grapes are intermediate in this respect.

The rate of respiration was found to increase from 1.89 to 3.01 times, an average of 2.376 times for each 10° rise in temperature for 49 sets of determinations with 40 different kinds of fruits. No stimulus in the rate of respiration due to picking was detected.

On the respiration of different floral organs, Mme. G. Maige (Ann. Sci. Nat. Bot., 9. ser., 14 (1911). No. 1–3, pp. 1–62).—The results are given of experiments with a large number of plants on the respiration of the sepals, petals, stamens, and pistils compared with each other and with the leaves, and of variations in the respiration due to the age of the floral whorls.

It was found in general that the intensity of the respiration in the floral organs is greater than that of the leaf. Of the floral organs the pistil respires the most actively. In the case of the stamens, the anthers present a respiratory intensity greater than the filament, which itself gives off more carbon dioxide than the leaves. The calyx was found to possess an active respiration considerably greater than that of the corolla, which equals or is less than that of the essential organs.
The intensity of respiration in proportion to the fresh weight of the floral organs decreases with age except in the case of the pistils, which often show increased respiration as long as they continue to develop. The intensity of respiration of the floral organs in respect to their age increases for each of the parts of the flower except the stamens, in which there is a falling off corresponding to the maturity of the pollen grain.

The respiratory quotient of the floral organs was found to be greater than that of the leaves, and the pistil greater than that of the stamens.

The reproductive frownd of the vascular cryptogams were found to have greater respiration than the vegetative ones.

**The influence of air currents on transpiration,** MAUD A. BROWN (Proc. Iowa Acad. Sci., 17 (1910), pp. 13-15).—This is a brief preliminary report on experiments to show the influence of air currents on the transpiration of Clivex and one of the Amaryllidaceae. The results show that in every case of plants exposed to the strongest current a checking of transpiration occurred, while gentler currents stimulated transpiration.

**The action of the osmotic pressure of the nutrient media on the form and structure of plants,** J. BÉAUVERIE (Rev. Gén. Bot., 23 (1911), No. 269, pp. 212-219, figs. 8).—The author gives the results of experiments on growing Aspergillus, Phaseolus, Pisum, Lupinus, Zea, and Triticum in various concentrations, with special reference to the modification in structure induced by the osmotic pressure of the nutrient media in which the plants were grown.

**Amyloclastic secretory capacities of the embryo and aleurone layer of Hordeum,** L. E. STOWARD (Ann. Bot., [London], 25 (1911), No. 99, pp. 799-841).—This is a study of the digestion and ultimate depletion of the storage-reserve materials of the endosperms of cereal seeds during the progress of germination, with special reference to the question of the vitality and auto-depletion of the endosperm. The phases investigated include the amyloclastic secretory capacity of the embryo and of the aleurone layer of barley and the relative amyloclastic secretory and self-depletive capacity of the endosperm and inner endosperm.

It is claimed that the experiments here reported prove that both the embryo and the aleurone layer possess an amyloclastic secretory capacity, but that the magnitude of the aleurone layer capacity is much the greater. The endosperm, by virtue of the secretory functions of the aleurone layer, was found to be capable of true auto-depletion.

**On the penetration of salts into the protoplasm and the nature of their toxic action,** J. DE RUFZ DE LAVISON (Ann. Scfi. Nat. Bot., 9, ser., 14 (1911), No. 1-3, pp. 97-189, fig. 1, durns. 6).—This is a more extended investigation of this subject than has been heretofore given by the author (E. S. R., 24, p. 532). It includes discussions on the general properties of colloids and of protoplasm, and on the general properties of salts in regard to their possible mode of action on the protoplasm together with the results of experiments on the penetration of salts into the protoplasm, and the action on and toxicity produced by these salts.

It was found that for weak solutions, cations of alkalis and alkaline earths combined with a nontoxic anion easily penetrated the protoplasm. The salts of barium, of caesium, and of iodin penetrated the protoplasm with difficulty. Certain salts of aluminum and yttrium and a large majority of the salts of the heavy metals do not penetrate the living protoplasm. Contrary to current opinions, the author found that the permeability of the protoplasm to weak solutions is an absolutely different phenomenon to its permeability by strong solutions. The protoplasm under the influence of strong solutions becomes completely permeable, without, however, being killed by those salts which in weak
solutions are unable to penetrate it. Protoplasm considered in its entirety as a membrane is then a modifiable membrane.

The author claims to have established 2 facts as to the toxicity of the salts:
(1) The toxic action of a molecule is approximately a property of acid and basic radicals for a large number of salts, while this is due to properties acquired by the molecule by reason of its nonsaturation by the acids and bases:
(2) the toxic salts are those which do not penetrate at all or only with difficulty the living protoplasm when they are employed in weak solutions, while solutions of nontoxic salts, on the contrary, easily penetrate the protoplasm. As to the nature of protoplasm it seems to be a very unstable substance as regards a large number of salts.

On the mineral nutrition of vascular plants based on the root structures, J. De Ruzf de Lavison (Rev. Gén. Bot., 23 (1911), No. 269, pp. 177-211, figs. 2).—In a further investigation on this subject (see above) the author holds in addition to the facts previously noted that the endodermis of roots acts as a sort of filtration medium for the salts able to penetrate the protoplasm, the intensity of this filtration power depending upon the nature of the plants, the kind of salt, and the age of the protoplasm of the endodermis.

The rôle of manganese in plant nutrition, P. Leibreiter (Studien über das Verhalten des Mangans im Boden zu einigen landwirtschaftlichen Kulturpflanzen (Hafer), Pferdebohne, Senf, Kartoffeln, Zucker- und Rübenkräutern. Leipzig, Diss., 1910, pp. 70; abs. in Ernähr. Pflanze, 7 (1911), No. 6, p. 53, fig. 1; Rev. Sci. [Paris], 49 (1911), t. No. 17, p. 536; Zentbl. Agr. Chem., 50 (1911), No. 8, pp. 531-535.)—Compounds of manganese have increased the yield of oats, mustard, beets, and potatoes. The green color was especially accentuated in the case of oats and beans, and the action of manganese manifested itself about the fifth week of growth. Beans were found to assimilate the largest doses of manganese, though an excess was easily shown to be injurious to them. Twenty-five mg. of manganese per liter of the nutritive solution was injurious to oats, and a solution of 0.5 zm. of manganese per liter killed oats after 2 months. Oats tolerated a greater proportion of manganese when grown in the soil than when grown in nutritive solutions. The addition of manganese to soils increased the sugar content of beets and the starch content of potatoes.

The action of manganese showed itself best on humus soils, to a less extent on clay soils, and least on sandy soils. It was found that the phosphate or nitrate of manganese was able to become a source of phosphoric acid or of nitrogen, the nitrate being absorbed most readily. Young plants were much richer in manganese than mature ones, while the leaves were the richest and the stems the poorest in manganese compounds.

A theory regarding the manganese soils and pineapples, C. C. James (Hawaii. Forester and Agr., 8 (1911), No. 6, pp. 176-178).—In a brief discussion of the manganese soils of Hawaii, the mineral content of pineapples and sugar cane, and the various manganic compounds, the author assumes that the toxic action of these manganese soils on pineapples is due to the action of calcium manganite primarily and to the secondary action of other salts and acids upon the calcium manganite.

The phosphorus assimilation of Aspergillus niger, A. W. Dox (Abs. in Science, n. ser., 34 (1911), No. 868, p. 218).—The author reports that a number of phosphorus compounds were readily utilized by this organism in culture media.

On the histological relations between Cuscuta and its host, Mary G. Thoday (Sykes) (Ann. Bot. [London], 25 (1911), No. 99, pp. 655-682, pls. 3).—This is a study of the origin of the protoplasmic connecting threads in plant tissues, in which by a careful histological investigation of the haustoria of
Cuscuta it is attempted to determine whether sieve plates are ever formed in compound walls separating the cells of the host from those of the parasite. After a brief discussion of the histology of Salvia and of Cuscuta, the author gives the results of her investigations on the relations that exist between host and parasite. The hosts examined were Salvia sp. (perennial) and Vitis sp., and the parasite C. reflexa.

It was found that the development of the sieve plates and sieve fields in the phloem of Salvia and Cuscuta agreed in all essentials with those of Vitis and Laminaria. The invading haustorium of Cuscuta was found to consist of a brush-like group of hyphae, the central ones of which push into the pith or fuse with the xylem of the host; the ones next surrounding these fuse with the sieve tubes, while the peripheral hyphae of the brush remain in the cortex. The main mass of the originally separate hyphae form in the mature haustorium, by lateral fusion with one another, a compact tissue. Each hypha composing the tissue becomes subdivided into a number of cells forming a strand. When the tip of the hypha is connected with a sieve tube of the host, this strand of cells develops into a strand of short sieve tubes. Connecting threads and sieve tubes are numerous in the subdivision walls, but are never found in the fusion walls between the originally separated hyphae.

Preparatory to the formation of a junction with a host sieve tube an invading hypha lays itself alongside the sieve-tube wall, so that the two come into lateral contact. The mucilaginous wall of the parasite where it touches a sieve area is then absorbed, and the naked protoplasm of the hypha applies itself to the sieve area of the host. The junction sieve plates and sieve fields in all cases exactly resemble those of the host under normal conditions. The translocation of food substances from host to parasite appears to be in the nature of a passive filtration. This arrangement probably disturbs as little as possible the normal mechanics of the sieve tubes of the host, and insures for the parasite a long-continued supply of food.

The influence of low temperatures on the distribution of the giant cactus, F. Shreve (Plant World, 14 (1911), No. 6, pp. 136-146, figs. 3).—From a study of the effect of freezing on the giant cactus the author comes to the conclusion that the occurrence of a single day without midday thawing, coupled with a cloudiness that would prevent the internal temperature of the cactus from going above that of the air, would result in the destruction of this species. A study of the climatological records and the known facts of its distribution seem to confirm this explanation of the limitation of its northern distribution.

Climatic selection in a hybrid progeny, D. T. MacDougal (Plant World, 14 (1911), No. 6, pp. 129-131, fig. 1).—A report is given on observations made on a number of acorns of Quercus heterophylla, a species believed to be a hybrid between the willow oak (Q. phellos) and the red oak (Q. rubra).

A number of these seedlings, which were obtained on Long Island, were transferred to the Desert Laboratory at Tucson, Ariz. The entire lot cast their leaves and were dormant on December 10, 1907. In 1909 the only plants which had survived were 5 of the narrower-leaved types, and in 1910 all had perished.

The observations seem to indicate that the qualities of the red oak were least favorable to endure the desiccating action of the desert climate. It was endured longer by the narrower and more indurated leaves resembling those of the willow oak.
FIELD CROPS.

[Field crops at the Kabeti Experiment Farm, 1909-10], J. Johnston (Dept. Agr. Brit. East Africa Ann. Rpt. 1909-10, pp. 119-143).—Meteorological data for 1909 and part of 1908 and 1910 are followed by numerous tables reporting the yields obtained in variety tests of numerous crops.

In experiments with Rose Coco beans it was noted that the variety with purple and black marked seed tended to suffer more from rust than the true type with rose-colored seed. An itemized statement is given for the cost per acre of maize grown in British East Africa.

In 2 year's tests of 8 different fertilizers and fertilizer mixtures for maize, the highest yield followed the use of 100 lbs. of sulphate of ammonia, while the application of 200 lbs. of kainit produced little observable effect.

In a test of 12 different fertilizers and fertilizer mixtures for wheat, the highest yield followed the application of 200 lbs. of superphosphate, this yield being even greater than that which followed the application of 400 lbs. of superphosphate. Similarly the use of 200 lbs. of basic slag was followed by higher yields than the use of 400 lbs. of the same material.

Annual report of the Lyallpur Agricultural Station for the kharif and rabi seasons, 1909-10, S. Milligan and D. Milne (Ann. Rpt. Lyallpur Agr. Sta., 1909-10, pp. 12-XL).—Although the use of soluble nitrogenous manures gave an increased yield of cane, this was entirely counterbalanced by a reduced percentage of raw sugar.

Rridge and flat plantings of cotton were followed by yields of 7.2 and 6.28 maunds (about 531.8 and 515.19 lbs.) per acre respectively, while subsoiling and ordinary deep plowing were followed by approximately equal yields. A test of the water requirements of American and Desi cottons showed that the former required 2 more waterings than the latter.

Deep cultivation and subsoiling were followed by approximately equal yields of wheat. A table states the results of a test of 20 varieties and strains of wheat. Applications of 112, 168, and 184 lbs. of calcium nitrate per acre were apparently followed by advances of 23, 2, and 4½ maunds respectively in yield of wheat per acre, but the residual value of the application was not ascertained.

Experimental work at Longerenong Agricultural College, J. T. Priddham (Jour. Dept. Agr. Victoria, 9 (1911), No. 3, pp. 151-155, figs. 3).—A brief report is given of the results of work with 4 generations of wheat resulting from 15 crosses which gave on the average a satisfactory percentage of grain. A variety test of oats is also reported.

Emergency forage crops, D. A. Brodie (U. S. Dept. Agr., Office Sec. Circ. 36, pp. 4).—This circular was issued July 7 in view of the reports of drought from the Central West. It gives directions for planting "quick growing crops that may be used as substitutes for the regular hay and pasture crops." Citations are given to other publications of this Department.

Forage crops for the sand-hill section of Nebraska, H. N. Vinall (U. S. Dept. Agr., Bur. Plant Indus. Circ. 80, pp. 23, figs. 7).—Suggestions and directions are given for growing alfalfa, clovers, and grasses in the sand-hill section of Nebraska, in view of the recent influx of settlers into this region.

Results of the cooperative demonstration work in the dry farming districts along the Santa Fé lines in New Mexico, J. D. Tinsley (Santa Fé Agr. Bul. 1, 1910, pp. 31, figs. 7).—This is the first of a series of bulletins to report the results of cooperative demonstration work conducted under the auspice of the Santa Fé Railway Company. Notes are given on the soil and climatic conditions of the region and on the crops. Samples of 32 varieties of corn were distributed but very few good ears were matured, although a few varieties
when favorably situated ripened nubbins. Nearly all the corn which matured was from native-grown seed of the Mexican June variety.

Leguminous crops for Hawaii, F. G. Krauss (Hawaii Sta. Bul. 23, pp. 30, pls. 8).—This bulletin gives directions for growing alfalfa, cowpeas, jack beans, pigeon peas, soy beans, and velvet beans in Hawaii. The results of experiments with some of these legumes are stated.

The author outlines methods for preventing cutworms from injuring alfalfa and states that seeding should be done in the fall months on account of the prevalence of cutworms. Experimental sowing with drills 12 to 24 in. apart used about 5 lbs. of seed per acre and even then thinning proved advantageous. Sowing with drills insures a more uniform stand, facilitates weeding, and if the rows are 20 to 30 in. apart renders horse cultivation for moisture conservation economical. Three varieties planted 5 ft. apart completely covered the intervening ground within 7 months of date of sowing and gave a green fodder yield of from 3 to 3½ lbs. per running foot at the first cutting and from 1 to 1½ lbs. per running foot of green fodder at subsequent harvests 30 days apart. These yields are somewhat less than those secured when rows were only half as far apart but greater than resulted from broadcast seeding. Greater yields per acre may apparently be obtained from row planting with proper cultivation and an optimum amount of water than from broadcasting with unlimited irrigation, and the relative cost of production by the 2 methods will depend on local conditions and the relative cost of water and labor. The irrigation methods in use are described.

Ten standard cowpea varieties and several hybrids have been tested for from 1 to 4 years, a spring and a fall crop being usually grown each year. Descriptions are given in order of merit of some of the varieties, including Whippoowill (No. 215), Iron (No. 274), Clay (No. 213) and Giant (No. 217). *Dolichos sesquipedalis* (No. 257), which closely resembles the cowpea, is also described.

The author describes the habit of growth of the pigeon pea and outlines a method of pruning during the first and second year's growth which results in bushy, heavy-yielding plants. Two crops were harvested during the succeeding 12 months. The plants produced at the rate of more than 2 tons of seed per acre during the first year and almost twice that amount during the second, the calculation being based on rows planted 10 ft. apart. It is being used by the horticultural department as shelter for young seedling citrus stock and a temporary wind-break for certain other crops. Few insect pests attack it.

Experimental plantings of soy beans produced from 600 to 1,000 lbs. seed per acre in case of dwarf early maturing varieties and about twice as much in case of medium late and medium tall varieties. The fodder yields of heavy seeding ran about equal to or slightly above the seed yields. At Kualapu un the velvet bean matured in about 165 days. At the station grounds experimental plantings gave uniformly good yields. In a growing season of 200 days the Lyon bean (No. 225) yielded at the rate of 3½ tons of seed and 17 tons of green forage per acre. The Florida bean (No. 226) yielded at the rate of over 6 tons of seed and almost 12 tons of green matter per acre.

An appendix reports the chemical composition and the fertilizing constituents per 1,000 lbs. of fresh material for Hawaiian-grown legumes of the kinds dealt with in this bulletin.

Grass culture, T. B. Hutcheson (Virginia Sta. Bul. 193, pp. 3-23, figs. 11).—Discussions of hay farming and soil fertility, hay buying in Virginia, the importance of pure seed, and the germination test are followed by recommendations of hay and pasture mixtures for various soils.

Orchard grass and clover mixed averaged 2,460 lbs. per acre in yield of hay during 1908 and 1909 as compared with 1,575 lbs. from orchard grass
FIELD CROPS.

alone. Timothy, redtop, and clover mixed yielded 5,440 lbs. as compared with 4,460 lbs. of timothy and redtop, 3,307 lbs. of redtop alone, and 3,857 lbs. of timothy alone. In 1909 spring and August seedlings yielded 1.86 and 2.1 tons per acre respectively of a mixture of sapling clover, timothy, and redtop.

An application of 1 ton of burnt lime and 300 lbs. nitrate of soda per acre was followed by an average hay yield of 4,402.5 lbs. per acre during 1909 and 1910 at Appomattox. Applications of 300 lbs. nitrate of soda and 1 ton of burnt lime produced yields of 3,127 lbs. and 3,699 lbs. respectively as compared with 2,215.5 lbs. per acre on the check plat. The same applications at Bowling Green during 1910 alone were followed by yields of 3,375, 3,160, 2,055, and 1,550 lbs. of hay per acre respectively.

In a test at Appomattox of the residual effect of fertilizers applied to tobacco during 1907 and 1908, applications of (1) 700 lbs. acid phosphate and 400 lbs. nitrate of soda, and (2) 400 lbs. bone meal were followed by the highest average hay yields during 1909 and 1910 from 8 different combinations of acid phosphate, sulphate of potash, nitrate of soda, and a 3:8:3 fertilizer. At Bowling Green 1,500 lbs. of cotton-seed meal applied to tobacco in 1908 was followed by a hay yield of 2,400 lbs. per acre in 1910 as compared with 1,200 lbs. after an application of 500 lbs. of a 3:8:3 fertilizer and an average yield of 1,040 lbs. on unfertilized plats. The author believes that potash applications to grass land do not pay except perhaps on sandy soils from which plant food leaches rapidly. Nitrate of soda was found to have little residual effect after 2 years.

Applications of (1) 100 lbs. of muriate of potash and 150 lbs. of dried blood and (2) 160 lbs. muriate of potash, 200 lbs. acid phosphate, and 150 lbs. dried blood were followed by yields of 3.12 and 3.18 tons of cured hay per acre at Blacksburg in 1909. In 1910, however, the highest yield followed an application of 200 lbs. of 16 per cent acid phosphate. Slightly increased yields also followed applications of 1 ton of burnt lime and 100 lbs. nitrate of soda per acre.

At the end of the third year after seeding a plat which produced a little over 1 ton per acre was plowed and reseeded without fertilizer. The next year it yielded 2.1 tons and the following year only 2 tons, indicating that timothy and clover deteriorate after the second year on this soil.

Grasses, A. M. Ten Eyck (Kansas Sta. Bul. 175, pp. 291-394, figs. 40).—Directions are given for growing, harvesting, and utilizing grasses adapted to Kansas conditions and experiments along these lines are reported.

During the 4 years 1905-1908 common alfalfa and Turkestan alfalfa excelled the other hay crops with yields of 8,426 and 6,875 lbs. of hay per acre respectively. Bromus inermis and alfalfa mixed yielded 6,576 lbs. and timothy alone yielded 5,528 lbs. It was noticed that the yields of B. inermis and meadow foxtail decreased each year after the first crop was cut. Orchard grass was less uniform in this respect.

During 1905 determinations of moisture in samples of various hays at stacking were made and are presented in tabular form. Figures for the years 1905-1908 and 1909 show that the moisture content of the same kind of hay may range from 13.95 to 31.45 per cent or even more widely in different years. Hay stored before it is fully cured "may readily lose 15 to 20 per cent in weight after being put into the mow or stack, due to loss of moisture alone." In 1909 the average moisture content of the 4 cuttings of alfalfa when stacked was 29 per cent. Green alfalfa shows about 80 per cent of moisture at the first cutting and 70 per cent at the second cutting. A table summarizes experiments in breaking and cropping prairie sod and reports the yields secured of flax, spring wheat, oats, corn, and other crops.
Winter cereals without irrigation, H. G. Mundy (Rhodesia Agr. Jour., 8 (1911), No. 4, pp. 584–591).—A discussion of the relation of winter cereals to dry farming is followed by a summary of the results obtained from experiments in Rhodesia.

The protein content of barley kernels, E. Speirling (Landw. Umschau, 1910, pp. 213–215; abs. in Jour. Landw., 58 (1910), No. 2, p. 135).—In 1907 strains of varying protein content were selected for sowing in 1908, when these variations in protein content appeared to be inherited. In 1909 such inheritance was not observed, the samples selected for high protein content being lower in this respect than those selected for low protein content.

Inheritance in maize, E. M. East and H. K. Hayes (Connecticut State Sta., Bul. 167, pp. 5–142, pls. 25).—This bulletin is strictly technical in character, reporting investigations carried on since 1906 at the Connecticut State Station and since the fall of 1909 at the Bussey Institution.

Earlier work on inheritance in maize and the ability of the corn plant to lend itself to individual analysis by the study of simple characters in carefully controlled pedigree cultures are discussed. The origin of the corn plant is considered and a description is given of the essential characters of each of the different subtypes. The principal object of the work is to determine whether the different characters under observation all obey the same law of heredity or whether separate principles are involved, and whether characters apparently inherited independently are not sometimes correlated with each other. The questions of the dominance of a character in the first generation of a cross and the purity of extracted homozygotes are also considered.

A description is given of each of 29 strains used in the work and the methods followed are described in detail.

Among the endosperm characters starchiness was found to be dominant over nonstarchiness. Tabulated data show that in all cases the average number of dominants and the average number of recessives accord with the expected 3:1 ratio of the Mendelian hypothesis. The dominant homozygotes bred true to the character of starchiness. All of the extracted recessives proved true to nonstarchiness except from the progeny of 1 ear which was nearly so. Taking the starchy and nonstarchy crosses as a whole, the authors consider that the mechanism by which the members of this allelomorph pair are distributed among the gametes is accurate.

The physical condition of starch behaves as a plant character affecting the whole ear. When crossing sugar varieties with starchy varieties it was found that starchiness was a separate plant character independent of the physical form in which it exists. Sugar varieties were found that were simply Dents and Flints which lacked starchiness.

The results from several crosses of Flint and Dent varieties show definitely that "the characters which give the Flint or Dent appearance to maize are transmitted to the entire ear and not as endosperm characters to the individual seed. They conform to the essential feature of Mendelism by showing segregation, and they are due to the action of more than one transmissible character." The proportion of corneous starch to soft starch depends partially upon size and shape of pericarp and upon the number of rows per ear.

Size characters such as number of rows per ear, height of plant, length of ear, and size of seed are complex in themselves as shown by the numerous varieties grown commercially and by the fact that they respond to environmental stimuli. "For these reasons we do not attempt to analyze our results further than to say that they do show segregation in every case. . . . Therefore we believe that size characters mendelize."
In some instances 2 yellow colors appeared in the endosperm each behaving when crossed with its absence as an independent allelomorphic pair. Both of these colors, although they behave in inheritance as separate entities, are either identical or very similar in composition. Data given show that in various crosses between varieties with white and yellow endosperm yellow was dominant and appeared as Xenia in the F₁ kernels. The F₂ kernels in their cross gave approximately the 3:1 (monohybrid) ratio. The F₁ kernels all showed the 3:1 ratio except one which showed the 15:1 (dihybrid) ratio. Dihybrid ratios were also secured in several other crosses. The F₂ seeds from the cross between a White Flour corn and a Yellow Dent made it evident that this combination was wholly monohybrid, having the 3:1 ratio. Among dihybrids the extracted dominants in the F₁ generations have in every case bred true.

The inheritance of the purple character was found to include also that of a hypostatic red color which appears in the crosses between the various purple and nonpurple families. The authors give exhaustive data on crosses between purple and nonpurple varieties. The results all tend to show, as they state, that the purple aleurone color behaves as a normal Mendelian character in inheritance. For example, in the cross between a White Flint and Black Mexican Sweet, the F₁ kernels formed in the hybrid seed were all purple. On growing these seeds 9 selfed ears were obtained. 7 of which proved to be monohybrid giving the 3:1 ratio, and 2 dihybrid giving a 9:7 ratio. In the F₂ generation 1 of the above dihybrid ears was tested. Nineteen selfed ears were obtained 2 of which were pure purple, 10 monohybrid, and 7 dihybrid.

The authors formulate the following law in regard to Xenia: "When 2 races differ in a single visible endosperm character in which dominance is complete, Xenia occurs only when the dominant parent is the male; when they differ in a single endosperm character in which dominance is incomplete or in 2 characters both of which are necessary for the development of the visible difference, Xenia occurs when either is the male."

The authors find in their studies of various plant characters that the podded character of the podded maize is dominant and behaves as a simple Mendelian monohybrid. Work carried on with regard to the factors which influence the development of the various red sap colors appearing in the pericarp, the cob, the husks, the silks, the glumes, and the authors shows that coupling sometimes occurred, but as a rule independent of the red in the other parts of the plant. Simple monohybrid results were obtained. Data given show that the red cob character is dominant to white cob and the red color in the silk to its absence.

Abnormalities are generally found to segregate but no further conclusions can yet be drawn on this point.

An extensive bibliography is appended.

Improvement in corn, H. K. Hayes and E. M. East (Connecticut State Stu. Bul. 168, pp. 3-21, pls. 4, figs. 1).—In this paper the authors discuss the disadvantages of the continued selection method of improving seed corn, and show that even with every precaution to prevent it selection tends toward inbreeding. Indian corn, as found in the field, consists of a number of types which have been brought together in the different plants by cross fertilization. Data are presented in tabular form which confirm this view and indicate that in nearly all cases the first generation of inbreeding has the greatest detrimental effect, and "that after a type has been inbred until it is in a pure state, continued inbreeding does not change its yielding ability." Inbreeding, therefore, has simply isolated the different types from the commercial variety.
Data given comparing crossed and selfed varieties with the parents show that the yield was increased in the first generation of the cross when the parents had been selfed for one or more years before the cross was made, and the increase in the first generation hybrid was found to be much larger than in the normal variety. Where the second generation crop was grown the yield was greatly reduced.

The results of a test of first generation hybrid corn, carried on in cooperation with several farmers in Connecticut, are given. Seven crosses between varieties were used and gave beneficial results in 5 cases, showing crops ranging from 7 to 44 bu. more for the hybrid than for the parent grown. The 2 crosses which proved no better than the parent varieties were also tested by the farmers who made them. A test of Watson White Flint × Woodbridge Yellow Flint gave a much larger yield for the crossed type than for Woodbridge parent, outyielding the parent by 17.2 bu.

The authors conclude that the production of corn by the utilization of the increased vigor due to a first generation hybrid is of commercial importance. Directions are given for the selection of parent varieties and for making the cross, and securing first generation hybrid seed every year for the commercial crop.

Experiments in potato growing, H. Henshaw (Jour. Bd. Agr. [London], 17 (1911), No. 11, pp. 892-904).—These pages report the results of numerous tests of seed of various potato varieties direct from Scotland in comparison with other seed grown out of Scotland for from 1 to 5 years.

In 1905 the use of seed of sizes ranging from 1¼ to 2½ in. resulted in crops varying directly in total weight with the size and weight of the sets planted, but more than twice as great a weight of diseased potatoes resulted from the planting of the largest sets. In 1906 and 1907 sets between 1½ and 1¾ in. and those between 1¾ and 2¾ in. yielded crops averaging 11 tons and 12 tons 3 cwt. per acre respectively, but the weights of marketable produce yielded were practically equal. The author notes that the kidney-shaped varieties do not give such satisfactory results when cut as do the round varieties.

Potatoes which had sprouted badly and from which the sprouts were removed before planting, produced somewhat higher yield in 4 tests conducted in 3 different years than did sound unsprouted potatoes. Variety tests are also reported. Numerous varieties, each purchased as genuine stock, are grouped on the basis of their close resemblance to 8 well-established varieties.

Standard and undesirable commercial types of potatoes, J. G. Milward (Wisconsin Sta. Circ. Inform. 26, folio; Sup.).—This circular is published in the form of a wall poster about 33 in. by 21 in., and is designed to bring about improvement in the uniformity and quality of car shipments, especially in connection with the use of the community center plan of seed distribution. It illustrates the standard types of Burbank, Early Rose, and Rural New Yorker potatoes and some undesirable types of each. It is accompanied by a supplement which illustrates 4 standard late varieties and the same number of standard early varieties.

A brief account is given of a plan for classifying the beets with reference to size, sugar content, and other characteristics. Notes on the work of 1910 are accompanied by tables presenting data on the mother beets, hybrid mothers, perennial mother beets, and the seed grown during that year.
How to grow wheat in Kansas, W. M. Jardine and L. E. Call (Kansas Sta. Bul. 176, pp. 3–28, figs. 4).—Experiments in 1910 testing 11 different methods of preparing a seed bed for wheat are summarized as follows:

Methods of preparing a seed bed for wheat.

The author discusses the value of the summer fallow to the dry-land farmer in western Kansas and considers briefly the 5 years' results comparing summer fallowing with continuous cropping as already reported (E. S. R., 24, p. 723). The author favors spring plowing for summer fallowing. Variety tests show that the hard red winter sorts, to which class Turkey Red and Kharkof belong, are best adapted to Kansas conditions. In the eastern tier of counties where semihumid conditions prevail the soft red winter sorts, such as Zimmerman, Pultz, and Currell, seem best adapted.

Methods of cleaning the seed, treating for smuts, and controlling insects and weeds are discussed, as well as cultural methods and quality in wheat.

Progress of wheat investigations, C. Willis and W. L. Burleson (South Dakota Sta. Bul. 128, pp. 133–144, figs. 5).—Statistical data on the relative acreage and yields of wheat and corn in South Dakota during each year between 1900 and 1909 inclusive, are followed by directions for wheat production in South Dakota. From the work done it appears that Turkey Red is one of the best varieties to plant. A test of fanned and unfanned seed of 3 varieties resulted in an average advantage of 1.43 bu. per acre in yield obtained from the fanned seed. Red Fife averaged 18.3 bu. per acre from 1905–10, excelling 13 other spring wheats, but early Java averaged 18.5 for 1900–10. In a test of 26 varieties of durum wheat Arnautka averaged 23.2 bu. per acre during 1901–2 and 1904–10, being excelled only by Arnautka 1,500. Arnautka 1,530, and Tagaro 1,570, which were tested during briefer periods. Descriptions of a number of varieties are followed by directions for treating seed for smut.

Garden and field seeds sold in Connecticut in 1910–11, Mary H. Jagger and E. H. Jenkins (Connecticut State Sta. Rpt. 1909–10, pt. 12, pp. 865–818).—Instructions for sampling seeds are followed by notes on the results of tests of alfalfa, clover, and grass seeds. A table shows in detail the results of each test made. The data presented includes the name of the dealer from whom seeds were secured, the weight per thousand seeds, the purity, germination, and viability percentages, and the percentage of inert matter and of foreign matter present.

Among 5 varieties of onions tested the minimum and maximum results were obtained from White Portugal and Wethersfield Red, of which 70.82 and 79.07 per cent respectively, sprouted. Of Connecticut and California grown seed stated to be less than 1 year old 74.72 and 88.18 per cent respectively, sprouted. In the
case of seeds stated to be between 1 and 2 years old the percentages were 65.58 and 77.46 respectively, as compared with 21.9 and 57.34 in case of seed reported between 2 and 3 years old, and 59.5 and 10 per cent in case of seed reported as between 3 and 4 years old.

The average vitality found in tests of 11 varieties of Connecticut-grown sweet corn ranged from 45 to 96 per cent. Better care in drying and storage is advocated.

In germination tests of pepper seeds "a 10-minute treatment of the seed with \( \frac{1}{2} \) and 2 per cent formalin seems to have only slightly improved germination although it reduced considerably the number of moldy seed."

The application of the frequency polygon in plant breeding, E. Zaleski

\( \text{Abs. in Jour. Landw., 58 (1910), No. 2, p. 140} \).—The author draws frequency curves and considers whether the more strongly marked deviations from the normal curves are due to unusual conditions of growth or to other disturbances. The polygons obtained from separate plates are united into summation polygons, and conclusions based upon the symmetry or the lack of symmetry of the resulting polygons are drawn.

Horticulture.

With the better understanding of cultural methods and the realization of the value of windbreaks, the quality of citrus fruits is improving considerably. Wild native oranges when picked in saleable condition sell readily along with the cultivated varieties. Much of the uncultivated citrus fruit has decayed in transit to New York. Experimental evidence indicates that in Porto Rico as in Florida and California (E. S. R., 20, p. S40) the main cause for decay is careless handling. In the cooperative fertilizer experiments with citrus fruits, the complete fertilizers continue to give the best results. Some experiments are being conducted to determine the influence of fertilizers on the production of out-of-season fruit which could be shipped either before or after the main crop has been shipped from California and Florida. In the variety tests with oranges, Hart Late has succeeded much better than any of the other varieties at the station. The trees of this variety, while bearing a heavy crop, remained vigorous during the long, severe drought of the winter and showed no detrimental effects from the excessive rains during the following summer. Rangpur limes which ripened in December, 1909, were left on the tree and were in good condition one year later.

In the orchard cover crop tests, plantings of a number of legumes were made. Of these Canavalia gladiata made the most rapid and vigorous growth, covering the ground in a few weeks after planting and smothering all grass and weeds. The plant continues its vigorous development until checked by the winter drought. Its extensive root system with its heavy top growth makes it valuable for lands injured by washing, though its vining habit is often troublesome in an orchard. The legumes are also being tested relative to their cropping value during the winter months.

The station now has 62 varieties of mangoes besides numerous seedling plants. Of the 6 varieties fruiting the past year, Sandersha was the most prolific, single trees bearing from 60 to 190 large fruits. Bulbulchasm and Cambodiana were considered the best in flavor. Many of the fruits of the latter variety, however, as well as a few of those of Sandersha were injured by fruit
flies when allowed to ripen on the tree. Until a means has been devised for the control of this fly susceptible varieties of mangoes cannot be recommended.

The Sandersha, Ameeri, and Cambodian mangoes were used in experiments to test the time for picking, methods of packing, and keeping quality. Fruit representing 3 stages of ripeness was gathered and stored in rooms of different temperatures. In a room with a temperature ranging from 80 to 83° F., a fungus disease injured many of the Ameeri and Sandersha fruits, they having probably been infected in the field. This disease did not affect the fruits of Cambodian or other varieties stored in a room with a temperature ranging from 42 to 48° F. Fruits almost ripe when picked softened within a few days in the warm room, the softening in the cold room being very much slower. Fruits picked while still solid, but mature, ripened in from 10 days to 2 weeks in the warm room, whereas they remained unchanged in the cold room for 60 days so far as could be observed. Fruits wrapped in oiled paper ripen more slowly and those infected with disease did not decay so rapidly in the cold room.

Owing to unfavorable soil conditions, trouble is still being experienced in bringing avocados to maturity in the station orchard, although within a short distance from the station in more open soils avocados flourish and produce excellent fruits. An attempt to domesticate such temperate-climate fruits as pears, peaches, plums, apples, and persimmons is not proving highly successful. Cultural and variety tests with vegetables were continued during the year. Good results were obtained in the experiments with yams and malangas and when a heavy application of stable manure was made a few varieties of melons in the fertilizer experiments did well.

Imported types of Curica papaya, including a superior type from Hawaii, fruited during the year but the fruit was seriously damaged by flies and other insects. The plantings of eucalypts, which are confined almost entirely to the flat, poorly drained soils, are showing considerable difference in thriftiness, Eucalyptus piperita and E. robusta having made the best growth. The latter trees 2 years from planting are 29 ft. tall. All of the varieties make a much slower growth in the absence of good drainage.

Frames as a factor in truck growing. W. R. Beattie (U. S. Depl. Agr., Farmers' Bul. 460, pp. 29, figs. 12).—This is a popular treatise on the utilization of frames for growing vegetables out of season. The author calls attention to the increased use of frames in the South Atlantic Coast States and discusses types of frames and their construction, soil and fertilizers, watering crops in frames, temperature, ventilation and protection, methods of handling a number of specific crops in frames, prevention and control of diseases and insects, and marketing frame-grown crops.

Fruit bud formation; progress of investigations in 1908, 1909, and 1910. B. S. Pickett (New Hampshire Stu. Bul. 153, pp. 36, pls. 2, figs. 6).—The investigation here reported deals with the question of fruit bud formation as influenced by the factors of cultivation, fertilization, and cover cropping.

The experiment was conducted in an orchard of 302 trees, mostly Baldwins and about 25 years old at the beginning of the experiment. The soil conditions are quite uniform throughout the orchard and the ground almost perfectly level. The orchard was divided into 11 plats, including a sod plat and plats on which the trees were given the following treatment: Cultivation with cover crop the odd year, seeded the even year; cultivation and cover crop the even year, seeded the odd year; clean culture throughout the whole season; cultivation and cover crop annually; root pruning; a normal complete fertilizer; excess phosphorus; excess nitrogen; excess potash; and liming. The data given for the first two seasons consist of counts of the average number of apples per tree in all the plats. The data for 1910 shows the yield of each tree in the
Although by orchard and the Rev., quantity systems investigation.

The results thus far indicate that clean cultivation up to July 10, followed by a cover crop of crimson clover, has given the greatest amount of fruit, although the plat on which cultivation and cover cropping was practiced 2 years in 3 gave almost as good results. In this orchard the inability of apple trees to produce fruit buds when grown in sod as compared with any of the systems of cultivation employed has been clearly and completely proved. Although the addition of fertilizers failed to stimulate a greater production of fruit buds, they improved the size and quality of the fruit. The largest quantity of No. 1 fruit per tree was produced in the limed plat, which plat included a section of the fertilized plats, and the next largest quantity of No. 1 fruit was produced in the plat receiving an excess of potash. The fewest No. 1 apples but the most highly colored fruit were produced by the sod plat. Excess phosphoric acid appeared to produce the smallest apples, though the fruit ran uniformly of good quality. The indications are that spraying has only an indirect influence on fruit bud formation. A general review of all results for 1910 indicates that a plentiful supply of moisture, the result of cultivation, was the most influential factor in stimulating the production of fruit buds. The addition of nitrogen in the form of a cover crop appears to be the second most important factor in this regard.

Variability of frost injury on fruit buds, Philena F. Homer (Mo. Weather Rev., 39 (1911), No. 4, pp. 599–601).—A review is given of the known causes of the differences in frost injury, together with observations on the variations in the killing power of frost that have taken place in the past 5 years on the Timpanogos Fruit Farm, at Pleasant Grove, Utah.

Preliminary frost fighting studies in the Rogue River Valley, C. I. Lewis and F. R. Baown (Oregon Sta. Bul. 110, pp. 62, figs. 19).—Preliminary orchard heating tests conducted in the springs of 1909 and 1911 are reported, together with observations taken in the different orchards throughout the valley, including experiences of some of the growers. A brief statement is also given of conditions in the Willamette Valley.

The tests made in 1909 were largely negative, owing to an inferior grade of oil, lack of sufficient heaters, and unusual low temperatures. In 1911 two orchards, consisting of 6½ acres of 17-year-old pears and 2 acres of apples, were heated with 2 types of sheet-iron heaters, one of which was the open lard-pail type and the other contained a center draft. Two grades of oil were used, 28° distillate and 20° "slop" distillate.

Although the latter part of March was very warm, 6 frosts were recorded from April 12 to May 5, the lowest temperatures for each being 29, 27, 25½, 28, 26, and 31° F., respectively. At 30° outside temperature no increase was obtained with 20 heaters per acre. With 39 center-draft heaters per acre an average increase of 1° was obtained. One hundred of these heaters arranged 17 by 25 ft. increased the temperature 3½°, and when arranged 21 by 21 ft. increased the temperature 4.1°. The lard-pail type of heater, when used at the rate of 100 per acre, arranged 17 by 25 ft., gave an average increase of 4°. When a carbon arrester was placed on these heaters, however, the increase was only 1.3°.

The heavy fuel oil left an inch of residue after each firing which would not burn, and if left in the heater decreased the burning time. Oils with a paraffin base are to be preferred to those having an asphalt base. Oil is considered the best fuel, as less help is required and an even temperature may be maintained. The average cost per acre for a 4-hour-period is $5.10 for oil, not counting the equipment. Heaters cost about 20 cts. each.
Although orchard heating systems are by no means perfected, it is concluded that under the conditions experienced in the spring of 1911, there is absolutely no doubt but that a crop can be saved by orchard heating. The rows that were heated in the apple orchard have a crop and the farther away the trees were from the heated area, the less fruit was saved. The results with pears were less conclusive, d’Anjou pears showing a slight injury from a late frost. Winter Nelis pears did not set a good crop, although this appears to have been due to general unseasonable weather conditions rather than to the effect of frost or smudging.

Although the temperature as recorded at Corvallis in the Willamette Valley dropped below 29°F on several nights and as low as 25°F at one time and was below 28°F for more than 2 hours, a fair crop of fruit is left, indicating that no arbitrary table of temperatures for frost injury has been worked out for all conditions.

Orchard heating, A. H. Thiessen (Mo. Weather Rec., 39 (1911), No. 5, pp. 761, 762).—A short descriptive account of methods of frost fighting as carried on in the Grand Valley, Colo.

Protection against frost—frost candles, A. G. McAdie (Mo. Weather Rec., 39 (1911), No. 5, pp. 769, 770).—A description is given of an inexpensive frost candle which has been devised recently at the San Francisco Weather Bureau office.

The frost candle, or cartridge, as it has been called, consists of a cardboard or stiff paper tube of suitable dimensions, filled with some combustible material, such as cotton waste and crude oil. A stopper is provided for the lower end and the projecting end of the cotton waste serves as a ready means of lighting. When used in an orchard the candle is suspended directly in the tree and about 6 in. beneath a metallic cover, which serves both to radiate the heat and to hold the soot particles that rise in the smoke. Cartridges have been made which burned for about 3 hours.

Winter vetch for a cover crop in Michigan orchards, H. J. Eustace (Michigan Sta. Circ. 13, pp. 1, figs. 5).—This circular contains a popular discussion of the value of a cover crop in an orchard or vineyard, and gives brief directions for the culture of winter vetch, which plant the Michigan Station found to be especially valuable for the purpose.

Strawberry culture in Idaho, C. C. Vincent (Idaho Sta. Bull. 70, pp. 50, figs. 28).—This bulletin contains a report on varieties of strawberries tested at the station for the past 3 years, considers the possibilities of strawberry culture in Idaho, discusses in detail the cultural methods employed by the leading growers of the State, and gives suggestions relative to systems of planting and subsequent treatment both in irrigated and nonirrigated regions.

Peach experiments 1906–1910, P. García and J. E. Mundell (New Mexico Sta. Bul. 76, pp. 42, figs. 10).—To gain more reliable data on peach growing in New Mexico, the station started an experimental orchard in 1906. This bulletin embodies the results secured through the season of 1910, the second year of fruiting. The orchard site is described and a detailed account is given of the preparation of the land, planting operations, cultivation, irrigation, pruning, varieties planted, thinning, picking, packing, and yields.

The trees were planted 20 ft. apart each way and headed at about 12 in. from the ground. Low heading has been an advantage in thinning and picking the fruit and it appears also to have helped in retarding sun scald on the trunk and larger limbs of the tree. The flooding system of irrigation was practiced and the trees were irrigated during the winter also without as yet producing any noticeable injury. An examination of the root systems of the trees made during the fall of 1910 showed a large root development, practically all of
which was between the second and fourth foot in depth of soil and spreading in all directions as far out as 15 ft. from the trunk.

Of the varieties tested Texas King has given the best results. Crothers is a fine late variety and a little sweeter than Elberta, which is apt to be injured by frost during the blooming period. The blooming and ripening seasons vary from year to year, depending on weather conditions. In 1909 late varieties bloomed about a week earlier and the fruit ripened a week later than in 1910. The blooming of earlier varieties in 1909 was retarded by a snowstorm. The ripening and shipping season of any one variety may vary from 10 to 15 days. Varieties which were not killed by frost yielded from 1 to 3 boxes in 1909 per tree and from 3 to over 5 boxes per tree in 1910. The actual net receipts after deducting all orchard operations from 4.82 acres of orchard in 1909 were $302.38 and $379.76 in 1910.

Experiments on the processing of persimmons to render them nonastringent, H. C. Gore (U. S. Dept. Agr., Bur. Chem. Bul. 141, pp. 31, pls. 3, figs. 5).—As noted in the introduction to the bulletin, by D. Fairchild, the experiments here reported are the outcome of the successful results secured by G. C. Roedling in 1905 and 1906 in the use of the Japanese method of processing persimmons in empty sake, or Japanese wine, casks (E. S. R., 17, p. 618). In view of these successful results experiments were conducted by the Bureau of Chemistry in cooperation with the Bureau of Plant Industry during the following 4 seasons.

The investigations from 1907 to 1909, the results of which are here summarized, consisted principally in attempts to improve the Japanese method. The use of the Japanese method was, however, but partly successful, even with the fruits which processed easily, because they often cracked as a result of the high humidity incident to the process and often softened unduly while in the casks or other containers employed.

During the season of 1910, an attempt was made to keep the fruit firm while being processed with vapors of alcohol by the use of some inert gas, such as carbon dioxide, the most readily available of these gases. These experiments, which are reported in detail, showed that if persimmons are kept in carbon dioxide for from 3 to 5 days during processing they become nonastringent and at the same time tend to remain firm, the lack of oxygen apparently retarding the life processes which result in softening. When carbon dioxide was used in the presence of alcohol vapors the rate of processing was at times more rapid than in carbon dioxide alone, but the fruits were less crisp and in 2 instances showed superficial injury. The absorption of moisture in the containers by well dried lump starch suggests the use of starch or some other absorbent as a means for preventing loss by cracking.

A number of varieties have processed successfully in carbon dioxide in from 3 to 5 days, but 2 lots of Japanese and the native persimmons (Diospyros virginiana) failed to do so. The rate of softening of persimmons was on the whole slightly but distinctly accelerated by processing. Overprocessing in carbon dioxide resulted in a large proportion of the persimmons becoming dark in color on softening subsequently. Processing persimmons in carbon dioxide after a cold storage interval of 27 days resulted in a rapid softening of the fruit after processing. Unsuccessful attempts were made to process the fruits by autoasphyxiation and by keeping them under water or other liquids. Chemical analyses of a number of varieties of persimmons have thus far shown no relation between the tannin content and ease of processing.

Although the present investigation is regarded only as preliminary, it is believed that the tentative results secured from the substitution of carbonic acid gas for the fumes of sake and the use of dry starch to prevent the cracking of the fruit during the processing should lead to the perfection and use of
this method for the production of nonastringent persimmons which may be
pared and eaten like an apple.

6).—After working with the date palm for a number of years and having
brought under control for the most part the active enemies of the palm, the
Arizona Station finds that the excessive waste due to insects, birds, and un-
timely wet weather remains a most serious drawback to the natural ripening
of the fruit, as high as 90 per cent of the crop having been lost during un-
favorable seasons. This, together with the almost complete failure of the
Deglet Noor date, which is the standard of excellence in the Sahara, to mature
and ripen naturally under Arizona conditions led to an attempt to devise a
rational method of artificial ripening. Two processes of artificial ripening
have been worked out, by the perfection and commercial adoption of which it
is believed the loss of fruit will be almost wholly saved.

Chemistry and ripening of the date, by A. E. Vinson (pp. 403–435).—The
author has continued his studies of date ripening and its economic application
previously noted (E. S. R., 19, p. 22; 20, pp. 61, 659; 23, p. 641). The present
report summarizes his investigations relative to date chemistry, including the
phenomena of natural and artificial ripening and the development of a suc-
cessful method of ripening dates through stimulation by chemicals at ordinary
 temperatures. Brief consideration is also given to the practical application of
this method and its commercial importance. The results of more immediate
practical application are summarized as follows:

"During the early period of its growth the date does not differ materially
from other nonstarchy fruits in the percentage of dry matter it contains.
After apparent maturity in size the rapid accumulation of sugar begins. This
continues till the date begins ripening. It is thus desirable, even if artificial
ripening is to be practiced, to leave the fruit on the tree as late as possible.
If cut too early, the flesh about the seed must necessarily be thin and insipid.

"Some varieties of dates begin ripening when they contain not more than
55 or 60 per cent of dry matter. Their sugar content is not quite high enough
to make them self-curing without further concentration of the juice. This
does not occur in humid weather, and fermentation soon starts which further
lowers the sugar content until the dates sour rapidly. Other varieties begin
to ripen only after a much higher percentage of sugar is present and conse-
quently are sugar cured before the protection of the living tissue of the unripe
date is broken down by ripening. These differences determine souring and
curing varieties.

"After dates have reached sufficient maturity they may be ripened artificially
either by heat or by chemical stimulation. The naturally ripened dates have
a delicate aroma which vanishes rapidly in the case of some varieties and per-
sists for many days with others, notably Deglet Noor. This aroma is not
developed by heat ripening. Many varieties ripen quickly after treatment with
various chemicals, of which acetic acid is the best in most cases. They may
be treated with the vapor of the strong acid or soaked a short time in vinegar.
Those that ripen after this treatment develop the aroma of the naturally
ripened fruit. Less responsive varieties, as Deglet Noor, yield readily to the
vapor of nitrous ether, which is effective in exceedingly small amounts. It does
not destroy the flavor and only slightly deepens the color.

"By the application of chemical methods of stimulating ripening, it will
probably be possible to ripen inferior varieties, which deteriorate rapidly, at
distant markets, and so to time the process that they may be delivered to the
consumer in their best condition. This process may make possible the use
of varieties which can be grown successfully under a wider range of climatic
conditions than the Deglet Noor."
Ripening dates by incubation, by G. F. Freeman (pp. 437-456).—The incubation method of date ripening first experimented with by Vinson but laid aside by him for chemical processes (see above) was in 1910 independently developed, amplified, and economically tested by the author, who, by its means, ripened and marketed the first successful crop of Deglet Noor dates from the Tempe cooperative orchards. The details of the incubation method are here presented, together with the results of chemical studies conducted to throw more light on the conditions affecting the ripening of the dates and with a view to possible improvements in the commercial processes.

The author recognizes 2 types of dates suitable for ripening—those which have passed the full mature green stage and are just beginning to soften naturally into a perfectly ripe condition, and those which have also passed the full mature green stage but are beginning to dry down into a mummy state. The first class is most suitable for ripening by incubation and seems to give the best fruit when ripened at a temperature of 45 to 48° C, for a period of 3 or 4 days. Mummy dates must be soaked in water for 6 or 7 hours before the incubation process commences. The same conditions of moisture and temperature used in ripening Deglet Noor dates were also favorable for great activity of the inverting agents present in these dates, hence the artificially ripened product differs from that naturally ripened in having nearly all its sugar in the inverted form. Although soaking in tenth-normal ammonia strongly lessens the inversion and gives dates of good taste and quality, this treatment is not recommended owing to conflicting opinions as to its effect on human health. The flavor of the artificially ripened, invert Deglet Noor dates is sufficiently fine to have thus far been accepted by the trade at fancy prices. An important effect of the temperature upon the dates which are ripened by incubation is the destruction of insect eggs which with the naturally ripened product often cause a considerable percentage of wormy dates after they have reached the market.

In view of the station's date investigations as a whole and particularly in view of the successful results secured from the incubation process of ripening, the planting of Deglet Noor palms in the Salton Basin, along the lower Colorado and in southern Arizona up to an altitude of 1,200 ft. is definitely recommended.

The relation of handling to decay in California navel oranges, season of 1910-11, A. V. Stuberbaugh (U. S. Depl. Agr., Bur. Plant Indus. Doc. 676, pp. 7).—In view of the heavy percentage of decay from blue mold observed in shipments of navel oranges early in the season of 1910-11, the Bureau of Plant Industry continued its handling and packing experiments along lines similar to those followed in the earlier investigations (E. S. R., 20, p. 43). The results are summarized in tabular form and discussed.

The average percentage of decay in all carefully handled oranges, including those brushed, washed, and not cleaned, was 2.8 as compared with an average of 14.9 per cent decayed for the commercially handled fruit. These results corroborate the results of the earlier work in every respect and show that even under the unfavorable weather conditions prevailing during the season fruit may be handled with sufficient care to insure its sound condition on arrival in market.

The new plantings of Porto Rican and foreign coffees are doing well. Several samples of roasted coffee were sent to different persons in the States and on the island, and nearly all reports from the cup trials agree as to excellency of the Maragogype coffee. A few trees of an excellent coffee, Mocha or Inham-
ban, were discovered near Mayaguez. Seeds of this variety are being propagated with the hope of introducing its cultivation among the planters. Leaf weevils are still doing much damage to coffee and experiments for their control have thus far been unsuccessful. Coffee leaf blight and borers in the shade trees continue unchecked thus far. *Stilbium flavidum* is spreading rapidly in the vicinity.

The crop of coffee in the 92-acre renovated grove was considerably damaged by storms, only 2,468 lbs. of coffee being harvested and marketed as compared with 2,723 lbs. in the previous year. The total cost of producing 100 lbs. of coffee was $5.25 and the average price obtained $11.03. Owing to the use of the crop from the young plantation for seed distribution and samples, no definite data were secured this year as to its cost.

The Department of Agriculture in relation to a national law to prevent the importation of insect-infested or diseased plants, James Wilson (U. S. Dept. Agr., Office Secretary Circ, 37, pp. 11).—In view of an evident misunderstanding as to the intent of the above proposed act in its relation toward nurserymen, the present circular contains a statement of the conditions calling for such legislation, a history of efforts to procure it, and an explanation of the scope and working of the bill now before Congress and the relation of the Secretary of Agriculture and his assistants to the enforcement of such a measure.

**FORESTRY.**

The prairies in Central North America and their value for forest culture, H. P. Baker (*Die Prärien in Zentralnordamerika und ihr Wert für Forstkultur. Inaug. Diss., Univ. München, 1911, pp. 94, figs. 11*).—This is a dissertation on this subject, based on a 4-years' study of that portion of the United States situated between the Mississippi River and the Rocky Mountains.

The subject matter is discussed under the 2 general headings of (1) the origin of the American prairies and the reason for their treelessness and (2) the future importance of forests in the prairie States. Suggestions are also given relative to reforestation.

On the basis of the results of his own study, as well as those of other investigators, the author concludes that the prairies of the Mississippi Valley were covered with forests in prehistoric times, and that the subsequent absence of trees on the prairies is due to a combination of causes, such as fire, wind, lack of rainfall, and unfavorable soil conditions. An increase in the cultivated areas and in the forest plantations will result in a considerable modification of the rough wind currents as well as certain increase of moisture and rainfall. Although conditions are not so favorable for tree growth as in the States east of the Mississippi, the control of prairie fires will render forest culture on the prairies profitable.

The management of Vermont forests with special reference to white pine, A. F. Hawes (*Vermont Sta. Bul. 156, pp. 99-139, pls. 8, figs. 8*).—The purpose of this bulletin is to describe the kind of thinnings and final cuttings applicable to the forests of Vermont, and especially to pine forests.

The phases discussed in part 1 include thinning and cutting, tree growth, improvement thinnings, removal of underbrush, pruning, final cuttings, clean cutting with planting system, and the natural reproduction of forests. Part 2 contains volume, yield, and growth tables for white pine as published by H. O. Cook (E. S. R., 20, p. 541). Part 3 contains suggestions for and specific examples of the management of pure and mixed white pine stands, together with a discussion of white pine seeding, market for pine, insects, diseases, and other enemies of white pine, forest fires, and grazing.
Windbreaks: Their influence and value, C. G. Bates (U. S. Dept. Agr., Forest Serv. Bul. 86, pp. 100, pls. 20, agms. 35).—This bulletin comprises a whole a consideration of the protective value of timber tracts. The study is based on a large amount of data collected in the Middle West, which show the effects of windbreaks upon field crops. From these data calculations of the net value of windbreaks to the average farm have been made.

Part 1 contains general observations relative to conditions in the region studied, together with a discussion of the important winds of the United States, the utility of windbreaks, how windbreaks act, and the system of measuring influences. Part 2 outlines the methods of measuring various physical factors, such as sunlight, soil moisture and fertility, mechanical power of winds, evaporation, heat, and humidity, and presents in several diagrams and tables the results obtained from measuring these various factors, together with the conclusions which may be drawn from a careful analysis of the effects of windbreaks on each factor influencing plant growth. Part 3 discusses the direct results of windbreak plantings as indicated by the yields and market values of timbers and presents data secured from plantations of cottonwood, green ash, silver maple, willow, honey locust, osage orange, Russian mulberry, catalpa, white pine, and Scotch pine. Part 4, which summarizes the investigation, discusses the calculation of the size of efficient windbreaks as determined by their value and form, gives a plan for the location of windbreaks on a 160-acre farm in the Middle West, together with suggestions for the establishment of windbreaks in the Northern Prairies, the Lake States, the Eastern States, and the Southwest States, as well as the fruit growing regions of the Pacific Coast States.

From the investigation as a whole the author concludes that the right kind of a windbreak in the right place is the source of profit and of comfort, and that it has a considerable esthetic value on the treeless plains of the Middle West. The prejudice which exists against the use of windbreaks is attributed to 2 things: First, experience with poorly planned and poorly planted windbreaks, and second, a lack of appreciation of the protection and profit which a windbreak affords.

National Forest Administrative Act (U. S. Dept. Agr., Office Solicitor Circ. 54, pp. 9).—The substance of the decision of the Supreme Court of the United States, including the opinion of the Court relative to 2 cases in violation of the National Forest Administrative Act of June 4, 1897, is given to show that the Supreme Court not only unanimously sustained the constitutionality of that act, but also the validity of the regulation of the Secretary of Agriculture requiring persons, who desire to pasture stock on the National Forests, to secure a permit and pay a fee therefor.

Forestry in Norway, S. B. Meyer (Jour. Bd. Agr. [London], 18 (1911), No. 5, pp. 385–394, pl. 1).—This comprises a sketch of the growth and work of the Norwegian government forest service, together with notable examples of private forest enterprises.

Annual progress report of forest administration in the Western and Eastern Circles of the United Provinces for the forest year 1909–10, P. H. Clutterbuck and H. Jackson (Ann. Rpt. Forest Admin. West. and East. Circles [India], 1909–10, pp. 18+7+18+XCIX+4).—This is the usual progress report relative to the constitution, management, and exploitation of the state forests in the Western and Eastern Circles of the United Provinces, including a financial statement for the year. The more important data relative to alterations in areas, forest settlements, surveys, working plans, forest protection and miscellaneous work, yields, revenues, etc., are appended in tabular form.

DISEASES OF PLANTS.

749, maps 3).—The research here reported comprises a combined botanical and chemical study of the Australian pines, undertaken to ascertain the extent of the commercial possibilities of these trees. Except where material was unprocu-

able, the species of some 12 genera are treated according to the following arrangement: Historical botany of the species; systematic descriptions; the leaves and fruit—economics, anatomy, and chemistry of the oils: the timber—
economics, anatomy, chemistry of its products, and forestry; and the bark—
economics, anatomy, and chemistry of its products. The more important results from the research are presented in summarized form.

From a botanical standpoint, the generic results of the research were greater than the specific results since the peculiarities of structure were found to be quite characteristic of and differing considerably from those of cognate genera.

Chemically and economically the results promise to be of great importance and to open new fields for commercial enterprise.

Seeds and seedlings of the conifers. R. Hickel (Bul. Soc. Dendrol, France, 1911, Nos. 19, pp. 13-115; 20, pp. 134-201, figs. 93).—This comprises systematic descriptions of the seeds and seedlings of coniferous trees. In a number of instances keys have been prepared for the determination of different genera and species by the characteristics of the seeds and seedlings.

Grafting the chestnut on other Cupuliferae, especially on the oak. PRUNET (Jour. Soc. Cent. Agr. Haute-Garonne, 20 (1910), No. 216, pp. 129-134).—As a result of several years' experimenting, the author concludes that grafting the chestnut on the oak or beech will always remain a botanical curiosity and will prove of no value in combating the ink disease of the chestnut. The planting of resistant varieties such as the Japanese chestnut is pointed out as the best solution for the problem.

[Experimental tappings with rubber], T. B. McClelland (Porto Rico Sta. Rpt. 1910, pp. 39, 40, pl. 1).—Some experimental tappings of 7 and 8-year-old Castilla rubber trees were made on the station grounds, the herringbone system being used. One of the largest of the 8-year-old trees tapped on April 15 and the wound shaved on April 18 and 20, yielded 40, 18, and 10 gm. of dry rubber for the 3 dates, respectively. Upon examination in August, the incisions made on the tree tapped in April seemed to have widened rather than to have made a successful effort in closing the wound. New incisions between the old scars gave almost no latex, but a good flow was obtained from the other parts of the tree. Since the cuts heal over very slowly, the herringbone system is not considered suitable for Castilla. Fourteen trees averaging 28 inches in girth and 3 ft. above the base were tapped in August yielding in all 279 gm. of dry rubber from latex and 70 gm. of scrap. The relative amounts of dry rubber bore no relation to the quantity of latex per tree.

DISEASES OF PLANTS.

Plant disease observations at the experiment station of the Swedish Seed Association at Ultuna, 1910, E. Henning (Svenskes Utsädesför. Tidskr., 21 (1911), No. 2, pp. 78-83).—Discussions are given of rust on winter wheat, the appearance of black rust on oats and barley, naked smut of barley, and other plant diseases observed during the summer of 1910.

material sent from the Malay Peninsula, Tropical Africa, Natal, and Queensland, among which is *Puccinia cymbopogonis*, a very destructive parasite on lemon grass in the Botanic Gardens at Eutebe, Uganda.

On a new organ of the *Mucorineae*, F. Guéguen (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 3, pp. 1684, 1685).—The author gives the morphological and cytological characteristics of certain peculiar bodies which were found on the hyphae of a new species of *Mucor* and suggests the physiological function of these bodies. The bodies, which are oblong and bladder-like, with digitate prolongations, were produced on sporophore-like structures and are supposed to be organs for the elimination of certain metabolic products of the fungus.

Some experiments with fungicides used for the prevention of stinking smut, F. Ditzell and R. G. Downing (Agr. Gaz. N. S. Wales, 22 (1911), No. 4, pp. 341-357).—This is a report of further experiments with fungicides (E. S. R., 23, p. 742). The relative efficiency of the various fungicides in destroying the bunt spores, the effect of the fungicides on germination, and the efficiency of each fungicide in preventing reinfection are given in tabular form.

Copper sulphate, copper sulphate and lime water, copper sulphate and salt (NaCl), copper sulphate solution in water, Fungusine, and Bordeaux paste all proved excellent preventives of bunt and each was also satisfactory in preventing reinfection, but the copper sulphate and salt solutions seriously injured the germination of the grain. Formalin, scalecide, and lysol were not regarded as satisfactory fungicides for the control of bunt.

On potato leaf blotch and leaf curl, A. S. Horne (Jour. Roy. Hort. Soc. [London], 36 (1911), No. 3, pp. 618-623, pl. 1).—The author describes the occurrence of a form of leaf curl in Scotland which developed on the President variety of potato, the seed tubers of which originated from tubers imported from Holland.

Plants grown from native seed tubers of the same variety were free of the disease.

The plants which were examined late in the season were stunted and yellowish with leaves more or less curled and marked with dark brown patches, much smaller and darker than those caused by the late blight. Cross sections of the blotched areas showed that the epidermal cells of both surfaces were diseased and discolored, especially the guard cells of the stomata. The disease extended inward to the palisade tissues and mesophyll and sometimes reached as far as the fibrovascular bundles, but there was nothing to indicate that the diseased spots originated from the bundles. Among the several kinds of spores found on the surface of the leaves were those of a *Macrosporium*.

It is suggested that the fungus associated with this disease exists on the skin of the potato, and that, owing to the elongation of growing organs, it is carried upward externally to the various parts of the plant.

Articles by the committee on the leaf-roll disease of the potato, F. W. Dafert (Ztschr. Landw. Versuchsw. Österr., 14 (1911), No. 5, pp. 757, 758).—This is a brief note on the personnel of the committee appointed to investigate the leaf-roll disease of the potato in general, and on the scope of the work.

Articles by the committee on the study of the leaf-roll disease of the potato.—II, Studies on the cause and propagation of this disease, G. Köck and K. Kornauth (Ztschr. Landw. Versuchsw. Österr., 14 (1911), No. 5, pp. 759-805).—As a result of their investigations, the authors decide that the leaf-roll disease can be propagated from one year to the next by means of diseased seed tubers, i. e., from seed tubers grown on leaf-roll diseased plants; also that infected soil is capable of producing the leaf-roll disease in plants grown from
sound seed tubers under conditions favorable for the development of the causative organisms.

After a discussion of the opinions of various investigators as to the cause of this disease, the results are given of chemical analyses and mycological studies of sound and diseased tubers. A mycological study of diseased tubers showed the presence of a Fusarium in the fibrovascular bundles in many instances, while in sound healthy tubers no mycelial threads were found.

A bibliography is appended.

**The leaf-roll disease of the potato,** R. Schander (*Ber. West Preuss. Bot. Zool. Ver.*, 32 (1910), pp. 70-77).—In a paper read before the thirty-second meeting of the West Prussian Botanical and Zoological Association held at Mewe in 1909, the author gives the symptoms, means of dissemination, effects on the yield, and methods attempted for the control of the leaf-roll disease of the potato.

On the American gooseberry mildew and the black wart disease of the potato.—II, Studies on the cause and propagation of this disease, K. Köck (*1911*), No. 5, pp. 565-568).—The authors give a brief history of the prevalence and dissemination of these two diseases and the remedies used for their control.

The relationship between the weather and grape mildew in Hungary, G. de Istvanfei and F. Savoly (*Rev. Vit.*, 35 (1911), No. 910, pp. 613-621).—A study is reported of the progress of the mildew in 1910 and of the climatic conditions of those regions in Hungary devoted to grape culture, including the winter weather for 1908-9 and 1909-10, changes of temperature, rains, humidity of the air, fogs, dews, cloudiness, and winds.

It was found that the mildew increased in direct proportion to the amount of precipitation; that humidity of the air was the most important factor in the appearance of the mildew, which was always preceded by a high degree of humidity in the regions in question; and that the weather during the winter did not appreciably affect the mildew but that the distribution of the rains in Hungary during April determined the locality of the first appearance of mildew, while the later rains during May and June determined the direction and intensity of its spread.

Comparative experiments with certain sprays for controlling the downy mildew (*Peronospora viticola*) of the grape, A. Bretschneider (*Ztschr. Landw. Versuchs. Österreich.*, 14 (1911), No. 5, pp. 806-813).—The effects noted as to the control of the downy mildew are given for (1) 1 per cent Bordeaux mixture, (2) 1 and 2 per cent solutions of Tenax, (3) 1 and 2 per cent solutions of Cucasa, (4) a 3 per cent solution of copper-soap mixture, (5) a 0.25 per cent solution of “Crystalazurin” solution, and (6) 1 and 2 per cent salt solutions made from certain rare earths.

**Apple rust,** N. J. Giddings (*Farm and Orchard*, 1 (1911), No. 12, pp. 3-5, figs. 3).—Attention is called to the general prevalence and severity in West Virginia during 1910 of this disease, which not only attacked the leaves, but severely infected the fruit. It is suggested that moist, warm weather during March or early April followed by cold weather during late April or May are important weather conditions favoring the infection of apple trees by the cedar rust. It would seem that the time of spraying rather than the kind of spraying is the most important factor in controlling this disease.

An uncommon disease of plum trees, F. T. Brooks (Gard. Chron., 3. ser., 49 (1911), No. 1276, p. 374).—Attention is called to the killing of Rivers Early plum trees in England by Dermatella pruniæ, a fungus which usually lives as a parasite only on the smaller branches of Greengage plum trees, causing a kind of die-back. In this instance it had attacked the larger branches and even the trunks of the trees.

Peach freckle or black spot, I. B. P. Evans (Agr. Jour. Union So. Africa, 1 (1911), No. 5, p. 696, pl. 1).—The author reports the prevalence of black spot (Cladosporium carophilum), especially on peaches, describes the general symptoms of this disease, and gives the remedies to be used in combating it. Three applications of Bordeaux mixture are recommended as the most effective treatment for the disease, the first application (5:5:45) 3 weeks before the buds begin to open, the second (4:4:100) just after the fruit is set, and the third (4:4:100) when the fruit is about half grown.

A leaf spot of the olive and curculio on almonds and peaches, B. V. Ramos (Bo1. Agr. Téc. y Econ., 3 (1911), No. 30, pp. 500–504).—Attention is called to a serious attack of leaf spot on the olive, caused by the fungus Cycloconium oleaginum, and of curculio on almonds and peaches.

The leaf blight of coffee caused by Pellicularia kolceroga has been studied, special attention being given to its life history. No asclerogenous stage was found, nor any evidence of propagation by spores. A slow but effective spread was found to occur by the dropping of the leaves carrying the mycelium, or their transportation by the wind to healthy trees, each infested leaf being a source of infection. During dry weather the fungus ceases to grow, gradually dries up, and falls away, but small fragments remain attached to the trees and from these a new growth develops when sufficient moisture is available. At the close of periods of drought is, therefore, the time when spraying can be made most effective. In spraying experiments with various fungicides Bordeaux mixture was found to be the best, owing to its adhering better to the foliage. Spraying, careful pruning, and avoidance of too close plantings promise to control this disease effectively.

A so-called root disease of coffee is noted, in which the trees are killed by being girdled just below the surface of the soil. At first the diseased area is small, but it gradually and slowly spreads. The trouble seems to be produced by the piling up of earth about the base of the trees and by the accumulation of masses of decaying vegetable matter.

The spot of leaf and fruit caused by Stilbum floridum is said to be a serious disease of coffee, but is restricted to a limited area of extreme humidity. The life history of the organism has been studied and experiments for its control are begun.

It is stated that the cultivation of pineapples in clay soils in some of the more humid regions is attended with uncertain results, as the plants during the second and third year become yellow and fail to respond to fertilizers. The roots of such plants are found to be decayed.

A Fusarium disease of bananas is also noted.
Report on the banana disease of Chinsurah, S. K. Basu (Dept. Agr. Bengal, Quart. Jour., 3 (1911), No. 3, pp. 196-198).—Attention is called to a disease which is said to be increasing to an alarming extent in certain parts of India. It is more common in old or neglected than in new or well-kept gardens.

The varieties Kauhtali and Martaman suffer most, while Champa and Kanche seem to be immune. The main symptoms of the disease are (1) the yellowing of the older leaves; (2) the formation of one or more much reduced leaves at the crown; (3) the gradual withering of the younger leaves, and (4) the final breaking down and death of the plant, which often occurs 10 or 15 days from the first appearance of the disease. Transverse sections near the base of the leaf sheath show black, brown or yellow spots from the size of a pin's head to circular spots 3 or 4 in. in diameter, while longitudinal sections show these spots extending as streaks from the roots upward into the rootstocks and leaf sheaths.

Microscopic examinations of the sections of the rootstock and leaf sheaths reveal the presence of hyalin or slightly colored septate hyphae in or near the fibrovascular bundles. In some instances colorless, oval spores of Cephalosporium, in balls or clusters on short stalks, were seen within the vessels, but in the course of a day the mycelium produced a new form of crescent-shaped spores corresponding to the Fusarium type. No higher forms of fructification than these were found although the original specimens were kept under observation for over 2 months.

The destruction of diseased plants, the use of healthy suckers for new plantations, and trenching around the new plantations are suggested as means of controlling this disease.

Three fungus enemies of orange trees, H. S. Fawcett (Proc. Amer. Pomol. Soc., 1911, pp. 190-196, pls. 2, map 1).—The author gives the characteristics of stem end rot (E. S. R., 25, p. 450), gummosis (E. S. R., 25, p. 456), and scaly bark (E. S. R., 25, p. 551), the damage done by each, and the methods for their control.

The brown spot of the navel orange, J. E. Corr (Cal. Cult., 37 (1911), No. 3, pp. 51, 52).—The symptoms of this storage disease of oranges and investigations as to its cause are given.

The disease is characterized by the formation of one to many irregular slightly sunken brown spots of about ¼ in. in diameter over the surface of the orange. These spots extend below the surface to about one-fourth the thickness of the rind. The spotting seems not to occur on fruit left late on the trees and is found so far only on the Washington navel orange. It is uniformly worse on fancy, smooth, thin-skinned fruit. No evidences of fungus or bacterial parasites have been found and the disease appears to be a physiological one somewhat similar to the bitter pit of the apple in South Africa. The results are also given of various experiments with the orange fruit concerning the probable causes of this disease, but nothing definite is reported.

The die-back fungus of Para rubber and of cacao, Thyridaria tarda n. sp., K. Bancroft (Dept. Agr. Fed. Malay States Bul. 9, 1911, pp. 28, pls. 3, map 1).—

The author gives the history, distribution, and symptoms of this disease and discusses the life history of the fungus, the relation of the parasite to the host, the nomenclature of the Diplodia condition of the fungus, sources of infection, the work of previous authors, and methods of treatment.

In a preliminary note (E. S. R., 24, p. 651) the author gave the results of certain cultural work in which the ascigerous stage of Diplodia cacaomicola was claimed to have been obtained. In this paper a more elaborate and detailed account is given of these experiments. It is claimed that successful inoculations and cross inoculations have been obtained with the ascospores of T. tarda on both cacao and Para rubber when the infecting material was applied to
wounds which reached to the wood of the tree. From the investigations on Para rubber and cacao it is claimed that the life history of the die-back organism consists of 3 forms, viz, the Diplodia stage for rapid reproduction, a Cytopspora form which develops on the plant some time after it has died, and the Thyrildaria stage which appears later, and which can infect the living plant with the production of the Diplodia form. The fungus must commence its existence on dead tissue, and having accumulated a mass of mycelium spreads to healthy parts of the attacked plant. The damage done by the fungus is closely related to the condition of health of the plant, and this is more evident in the case of older plants.

The occurrence of burs on the trunk of Hevea brasiliensis, K. Bancroft (Agr. Bul. Straits and Fed. Malay States, 10 (1911), No. 5, pp. 138-141).—Attention is called to the occurrence of exocrescences or burs on the trunk of H. brasiliensis in the Federated Malay States. These burs are referable to 2 distinct sources. One type occurs on untapped trees as well as tapped, while the other type is distinctly the result of wounding by tapping.

The burs of the first type originate as small structures, raising the outer surface of the bark in lumps and in this condition they are known as the "pea disease." Arising in the cortex they have at first no connection with the main wood of the plant, but by continual growth and fusion with each other large structures are produced of irregular shapes, often several feet in size. At first these are superficial to the latex layer, but by further growth they fuse with the main wood and the intervening latex and cambium layers are squeezed out of existence. Each nodule possesses a central woody core composed of vessels which are for the most part irregularly arranged: outside the core is a layer of cambium which produces a slow growth by the addition of wood to the central woody mass. The commonest cause of the production of burs of this type is the wounding of the cortex, such as by the grazing of a cart wheel. Also many of them in their nature and mode of origin seem to be buds which have failed to develop into shoots.

The second type of burs is apparently caused by the tapping knife severing the cambium and wounding the wood.

Nut diseases; with special reference to the pecan, M. B. Waite (Proc. Amer. Pomol. Soc., 1911, pp. 182-190).—In addition to a general discussion of the diseases of the pecan, the author notes a disease of the English walnut (Pseudomonas juglandis), almond leaf-blight (Cytopspora circumcissa), the gumming fungus (Coryneum beyerinechii), the crown-gall (Bacterium tumefaciens), and the chestnut disease (Diaporthe parasitica). The following pecan diseases are noted, their charateristics given, and methods for their control suggested: Pecan scab (Fusidium effusum), the most serious disease of pecans in the Southeastern States (E. S. R., 21, p. 452), pecan rust (Helminthosporium arbuscula), mildew (Microsparrha alni), leaf blight (Cercopora halsidii), root rot (Fusarium sp.), pecan rosette, winter kill, and pecan drop, which is characterized by the shedding of nuts of various sizes, due apparently to a physiological cause.

Notes on fungus diseases, L. H. Pammel (Abs. in Science, n. ser., 33 (1911), No. 862, p. 28).—At the April meeting of the Iowa Academy of Sciences attention was called to a very destructive Exosascus on the hard maple in the Rocky Mountains, an Exosascus on the oak, Fomes ignarius on the quaking aspen in the Wasatch Mountains in Utah, and a Pleurotus on box-elder and other deciduous trees in Iowa.

timber in which light or dark violet to dirty red-colored spots and larger areas of grays to grayish brown appear in the wood. This staining, it is claimed, is due to the fungus, Z. resinae. The characteristics of the fungus and its synonymy are discussed.

Blue stain on lumber, Caroline Rumbold (Science, n. ser., 34 (1911), No. 864, pp. 94-96).—The results are given of experiments with different chemicals in preventing the blue stains on lumber caused by fungi, especially by certain species of Ceratostomella and Graphium.

Sap boards of yellow pine, red gum, green yellow pine, and green red gum were dipped in hot and in cold solutions (from 1 to as high as 10 per cent) of sodium carbonate and sodium bicarbonate, after which the boards were inoculated with the spores of C. echinella.

These tests showed that an 8 per cent solution of sodium carbonate was as effective as an 11 per cent solution of sodium bicarbonate. These strengths prevented blue staining on red gum when the weather was rainy, while in dry weather a 5 per cent sodium carbonate and a 4 per cent sodium bicarbonate solution kept yellow pine boards unstained.

Freshly cut red gum and yellow pine sap boards required 8 per cent sodium carbonate and 10 per cent sodium bicarbonate solutions to prevent blue staining when the fungi were growing vigorously. A greater resistance to the alkali in the medium was shown by the spores of Ceratostomella than by the mycelium.

A disease of orchid leaves, F. T. Brooks (Gard. Chron., 3, ser., 59 (1911), No. 1281, p. 27).—Attention is called to a recent outbreak in the orchid house at the Cambridge Botanical Garden of leaf spot (Hypodermium orchidicarum) on the leaves of different kinds of orchids, including species of Thunia and Dendrobiurn.

The disease begins at the apex of the leaf and spreads downward, producing a discoloration of the affected areas and finally the death of the leaf. It is checked by sponging the leaves with a dilute solution of potassium permanganate.

Extermination of eelworms, J. Smith (Gard. Chron., 3, ser., 59 (1911), No. 1280, p. 7).—It is claimed that by top-dressing the pots containing the infected plants with rape meal the eelworms in the soil are destroyed and the diseased plants benefited.

The chemistry of lime-sulphur wash, W. B. Burgess (Journ. Southeast. Agr. Col. Wyc, 1910, No. 19, pp. 61-69).—The author gives the results of investigations as to the most satisfactory proportion of lime and sulphur for making the wash, and as to the chemical changes which the mixture undergoes when exposed to the air under conditions similar to those which obtain when it is used as a summer spray. No definite conclusions were reached as to the exact proportion between the lime and sulphur but on the whole the most satisfactory ratio seems to be from 150 to 200 lbs. of sulphur to 100 lbs. of lime.

In testing the behavior of the mixture when exposed to air, the amounts of polysulphid and thiosulphate sulphur and of lime were determined. A given amount of the mixture was then exposed to the air and these constituents again estimated. It was found that the wash as a summer fungicide acts in 2 distinct ways, (1) as a contact spray, the polysulphids acting in a way similar to potassium sulphid, and (2) as a protective coating to the leaves, due to the thin layer of finely divided sulphur deposited from the thiosulphates and polysulphids by decomposition.

Some recent experiments with lime-sulphur spray, E. Wallace (Proc. Amer. Pomol. Soc., 1911, pp. 272-281).—This paper is a summary of conclusions, the subject matter of which is embodied in 3 New York Cornell Station bulletins, all of which have been previously noted (E. S. R., 25, pp. 47, 48, 49).

ECONOMIC ZOOLOGY—ENTOMOLOGY.

A biological survey of Colorado, M. Cary (U. S. Dept. Agr., Bur. Biol. Survey, North American Fauna No. 33, pp. 256, pls. 12, figs. 39).—This report consists of 3 sections. The first characterizes the 5 life zones which traverse the State, defines their extent and limits, and discusses their agricultural and economic possibilities. The second consists of a complete list of the mammals of Colorado, with brief notes on their habits, distribution, and economic relations. The third is a list of the principal trees and shrubs of Colorado observed by the assistants of the Biological Survey during the progress of the work in the State with annotations as to their distribution and abundance.

A colored map of the life zones of Colorado and a complete index of the subject matter are included.

The mammals of Bitterroot Valley, Mont., in their relation to spotted fever, H. W. Henshaw and C. Birdssee (U. S. Dept. Agr., Bur. Biol. Survey Circ. 82, pp. 24, figs. 12).—This is a report of investigations carried on from March 12 to July 14, 1910, and continued in 1911 in cooperation with the Bureau of Entomology and the Montana Station. It also embodies numerous data obtained by assistants of the Biological Survey in previous years. The investigations were undertaken for the primary purpose of ascertaining the particular species of wild mammals in and near the valley which harbor ticks, especially Dermacentor venustus, the species chiefly responsible for the spread of Rocky Mountain spotted fever.

“The almost complete restriction of the fever to the western side of the valley has occasioned much speculation and given rise to a theory of its possible connection with some native mammal or mammals living solely on that side; but a study of the range of the mammals of Bitterroot Valley has failed to show that a single species is restricted to the western side. Nevertheless the two sides differ physically so widely as to influence greatly the distribution of mammals. On the west side the mountains rise abruptly, forests or brush covering much of the land except the cultivated tracts; while on the east side a strip of rolling, treeless, sage-covered bench land lies between the river and the mountains. Thus the west side has a somewhat more humid climate than the east, with heavier growth of brush, which furnishes good cover for most of the small mammals, and hence favors the presence of ticks. But on the opposite or less humid side good ‘tick country’ occurs only around those ranches which nestle close up to the mountains. Ground squirrels, chipmunks, woodchucks, and pine squirrels—animals which were found to be the principal hosts of the nymphs and seeds of the fever tick (D. venustus)—are mainly absent from the broad strip of sage-covered bench land.”

In the course of the investigations more than 500 mammals were collected and around the valley and 20 species were found to carry ticks either in the immature or adult stage. “The hosts of fever ticks fall naturally into 2 groups, those that harbor chiefly adult ticks and those that harbor the younger stages. In the former class belong mountain goats, bears, coyotes, badgers, woodchucks, and possibly elk, deer, mountain sheep, rabbits, and domestic stock, as horses, cattle, and sheep. Those of the second class, mainly rodents, comprise ground squirrels, woodchucks, chipmunks, pine squirrels, mice, and wood rats.”

Experiments are now being made in the Bitterroot Valley to discover the most practical methods of destroying the several species of mammals that act
as hosts for the fever tick. Brief accounts are given of the various mammals of importance and methods for their destruction. An annotated list of the mammals found in and near the Bitterroot Valley, Mont., together with reproduced photographs of many of the species is presented by C. Birdseye (pp. 9-24).

Three important wild duck foods, W. L. McAtee (U. S. Dept. Agr., Bur. Biol. Survey Circ. 81, pp. 19, figs. 19). — The vegetable food of wild ducks includes a large variety of plants of which wild rice, wild celery, and pondweeds have been found of especial importance. In the case of 16 of the more important species of game ducks, the stomachs of which have been examined, these 3 foods collectively composed 25.31 per cent of the total food. Their value as duck food is discussed, together with descriptions of each, their distribution, transplantation, and enemies. It is stated that all 3 can be propagated in suitable waters anywhere in the United States.

Directory of officials and organizations concerned with the protection of birds and game, 1911, T. S. Palmer (U. S. Dept. Agr., Bur. Biol. Survey Circ. 83, pp. 16). — This, the twelfth annual directory of officials and organizations concerned with the protection of birds and game in the United States and Canada, is revised to July 15, 1911. The arrangement is the same as that of previous issues (E. S. R., 23, p. 554).

The guava fruit fly, which infests practically all the fruit, and 2 beetles the larve of which feed on the fruit, are said to be the most destructive of the insects attacking the guava. An ant, which lives in the coffee shade trees and occasionally in the coffee itself, is the source of serious injury to coffee. Successful results are reported to have been obtained from the fumigation of citrus trees. At the present time there seems to be a bright future for the bee industry in Porto Rico as there are no diseases, and where Italian bees are used bee moths are not troublesome. A law intended to prevent the introduction of bee diseases was passed by the last session of the legislature.

A trip to Cuba was made in June and July, 1910, with a view to studying the sugar cane insects of the island and obtaining parasites of the Lachnosterna beetle. However but 2 specimens of this beetle were found. Many of the planters recognized it from descriptions given and all stated that its flight occurred during March, April, and May, which is the same time that its flight takes place in the district of Mayaguez, Porto Rico. The flight of this beetle was found to be the same in all parts of Cuba visited, namely, Santiago de Cuba, Habana, Ceballos, Cienfuegos, and Manzanilla. The sugar cane insects of Cuba are said to be similar to those of Porto Rico.

The insect pest of the Mokameh Tal lands, E. J. Woodhouse and H. L. Dutt (Dept. Agr. Bengal, Quart. Jour., 4 (1911), No. 4, pp. 198-213, maps 2). — The cutworm Agrotis ypsilon has been found to do serious damage in the Tal lands in the vicinity of Mokameh. It produces 2 broods a year on these lands, the second brood being responsible for the damage. Prodenia littoralis appeared as an accidental pest in 1910.

Insects in a quantity of castor cake and stored grains in the central seed store (Dept. Agr. Bengal, Quart. Jour., 4 (1911), No. 4, pp. 213-216).—This is a brief report of insects affecting stored grain in Bengal.

The Indian-meal moth and "weevil-cut" peanuts, C. H. Popeneoe (U. S. Dept. Agr., Bur. Ent. Circ. 142, pp. 6, fig. 1).—The advent of the mechanical thresher has resulted in a much larger percentage of broken peanut shells, it being estimated that between 20 and 30 per cent of the peanuts are injured in this manner. Consequently they become seconds and in nearly every case infestation follows in a very short time after they are stored. In a footnote, F. H. Chittenden estimates the loss to the peanut dealer at 20 per cent, or at a conservative estimate $3,000,000, for 1910. This is based on the assumption that the percentage of the insect injury is the same as that to stored cereals. The practice of piling sacked nuts high in the storage warehouses, which makes it necessary for workmen to climb upon the stacks, thus breaking many more, also increases the percentage of infestation through affording ingress to the pests.

The Indian-meal moth (Plodia interpunctella), a common and well-known pest, habitually frequenting all places where foodstuffs and cereals may be stored, is the insect chiefly concerned. "In addition to the Indian-meal moth, several other insects are frequently found to injure peanuts in storage. These, in the order of their importance, are as follows: The rust-red flour beetle (Tribolium navale), the saw-toothed grain beetle (Silvanus surinamensis), the cadelle (Tenebroides mauritianus), the fig moth (Ephestia cautella), and the Mediterranean flour moth (E. kuchniella). The 3 former species are capable of cutting through the shells of peanuts, but rarely occur in such numbers as to be injurious to them."

Descriptions are given of the stages of the Indian-meal moth, its life history and habits. It has a number of natural enemies, of which the 2 hymenopterous parasites Omorgus frumentarius and Hadrobracon hebetor are the most important. Remedial measures are considered under the headings of heat and fumigation. The author reports having used the heat treatment very successfully in a peanut mill in Virginia.

"Sufficient radiator surface should be supplied to obtain a temperature of 120 to 125° F. A few courses of 1½ in. pipe placed along the side walls should easily bring about the desired results. . . . To permit the most effective penetration of the heat, the bags of nuts should be piled only a few feet deep, as experience has shown that some time is required for the peanuts within the piles to be raised to a uniform high temperature. The building should be closed tightly and the temperature raised to 120° F., remaining at this point for at least 6 hours. . . . The temperature should not be raised above 125° F. in the case of peanuts, as experiments have shown that a slight degree of blanching, or slipping of the ‘skin’ takes place in shelled Spanish nuts exposed to such a heat. . . . Germination is likewise unaffected, peanuts exposed 6 hours to a temperature of 140° germinating better and more quickly than those unheated. A temperature of 116° is fatal to insect life in a short time, larvae, pupae, and adults of the Indian meal moth dying in less than ½ hour, when exposed."

Care should be taken that the factory is kept free from an accumulation of moths during the summer. To this end, all cars of infested peanuts coming into the factory should be fumigated before entrance. Preventive measures to be made use of by the grower include the proper selection and operation of the peanut picker or thresher and the disposal of all nuts before June 1.

Heat as a means of controlling mill insects, G. A. Dean (Jour. Econ. Ent., 4 (1911), No. 2, pp. 142-158, charts 9).—The author reports laboratory and mill
experiments conducted in order to determine the amount of heat necessary to kill the important mill insects.

In a laboratory series of experiments in which all stages of *Tribolium confusum*, the larva and pupae of the Mediterranean flour moth, and adults of the rice weevil and of *Tenebrio ides mauritanicus* were used, a temperature of 115° for a period of 12 hours proved fatal to all.

The mill tests were made in a 4-story building with heavy brick walls, tight wooden floors, and no basement. All stories being heated with steam and well filled with machinery. In a test in which heat was applied for 24 hours and the maximum temperature registered was 105° on the first floor, 133.5° on the second, 141° on the third, and 128.6° on the fourth, all the insects on the 3 upper floors, including the larva, pupae, and adults of *Tribolium confusum* and several other common mill insects, were killed with the exception of one corner on the fourth floor. Upon a second examination of the mill 3 weeks later, no live insects of any sort were found above the first floor.

**Citrus fruit insects**, H. J. Quatle (California Sta. Bul. 214, pp. 443–512, figs. 74).—A summarized account of 19 of the more important insect enemies of citrus fruits, their natural enemies, and means of control. Methods of fumigation are briefly described and the text given of the section of the state law on orchard and nursery inspection.

On some important insect pests of the Coniferae of the Himalaya with notes on insects predaceous and parasitic upon them, E. P. Stebbing (Indian Forest Mem., Forest Zool. Ser., 2 (1910), No. 1, pp. 1–7, pl. 1).—In this the first part of the volume, insect pests of the deodar (*Cedrus deodara*) are dealt with. Four species are described as infesting the bast layer of the main stem and the larger branches of old trees, 2 as infesting the main stem of saplings and poles, 3 as infesting the crown and leading shoots of saplings and seedlings, 5 as infesting the twigs and buds, 2 as infesting the needles, 2 as infesting the cone, 3 as infesting the root, and 1 as infesting the wood.

**Oviposition among tree crickets**, P. J. Parrott (Jour. Econ. Ent., 4 (1911), No. 2, pp. 216–218, pl. 1).—This paper deals with observations upon the egg-laying habits of *Ecanthus niviscus*, *O. nigricornis*, and *O. quadripunctatus*.

The author found that when apples and raspberries were grown together in the same cage *O. niviscus* invariably laid its eggs in apples, but that in the absence of other plants it would deposit eggs in raspberries. *O. nigricornis* and *O. quadripunctatus* always preferred raspberries, but when *O. nigricornis* had no alternative it sometimes laid eggs in apple wood, usually selecting the tips of the new growth.

**Economic importance of Stictocephala**, H. Osborn (Jour. Econ. Ent., 4 (1911), No. 2, pp. 137–149).—The author reports that *S. festina* has been found to injure alfalfa in Louisiana through puncturing and sucking sap from the stems. In some instances it has been observed that the punctures have been made in a series surrounding some of the stems, and as a result of this attack the plants above the point of puncture wilt and die.

**The woolly aphis**, Schizoneura lanigera, H. W. Lohrenz (Jour. Econ. Ent., 4 (1911), No. 2, pp. 162–170, pl. 1).—Spraying experiments with kerosene emulsion are reported, together with biological notes.

**Macrosiphum destructor** and *M. solanifoli*, Edith M. Patch (Maine Sta. Bul. 190, pp. 81–92, figs. 14).—This is a discussion of the structural characters, classification, and biology of *M. destructor* and *M. solanifoli*, the exact position of which has not as yet been determined. On account of the uncertainty as to whether or not "*pisi*" is a composite species in Europe as well as in America, both in collections as well as in literature, the author leaves the problem to European investigators to work out. In this bulletin she discusses
the "destructive green pea-louse" of America under the name of *M. destructor*. Whether *M. reticulata* of Sanderson may prove to be *M. solanifoli* or not, the author has at present no biological evidence to indicate, but the structural character of the antennae and cornicles separate *M. reticulata* from *M. destructor* and show that it is at least closely allied to *M. solanifoli*. Technical descriptions of the winged viviparous, apherous viviparous, and apherous oviparous females and winged male of *M. solanifoli* are followed by detailed descriptions of insectary host plant tests for both.

A bibliography is appended.

**The rufous scale at Key West, Florida, A. W. Morrill** *(Jour. Econ. Ent., 4 (1911), No. 2, p. 277).*—The author records the occurrence of *Selenaspidus arcticulatus* in the United States.

**Spraying for the euonymus scale**, Z. P. Metcalf *(Jour. Econ. Ent., 4 (1911), No. 2, pp. 259–261).*—The author’s experiments led him to conclude that early March, early June, and early August are desirable times to spray for this pest in North Carolina. The spraying experiments lead to the conclusion that "of the 3 materials tried, scalecide, 1:10 in winter and 1:25 in summer, would rank the highest. Next to this we would place kerosene emulsion, 60 per cent in winter and 30 per cent in summer. Either one of these materials seems to be an effective remedy for the euonymus scale. Our experience goes to show that these strengths may be used without any danger of injuring the plant. Commercial lime-sulphur did not prove to be an effective remedy in any of the strengths used, although the hedge sprayed with commercial lime-sulphur showed decided improvement over no spraying at all."

**The San José scale and how to control it**, P. Hayhurst *(Arkansas Sta. Bul. 107, pp. 369–393).*—This general account of the San José scale, which is increasing in importance in Arkansas, replaces Bulletin 102, previously noted (E. S. R., 20, p. 655). *Aphelinus fusicipennis*, *A. mytilaspidis*, *Abierus elisiocampe*, and *Aspidiotiphagus citrusinus* have been found by the author to occur in Arkansas as parasites of the San José scale.

**Two important cantaloupe pests**, R. I. Smith *(North Carolina Sta. Bul. 214, pp. 101–116, figs. 17).*—This general account includes a report of life history studies of the pickle worm (*Diasphania nitidalis*) and the melon worm (*D. hyalinata*), 2 of the worst pests of cucurbitaceous crops, especially of cantaloupe, squash, and cucumbers. In Georgia and Florida these 2 species are often of about equal importance, but in the vicinity of Raleigh where the author’s investigations have been conducted for the past 2 seasons, and over the greater portion of North Carolina, the pickle worm is more injurious than the melon worm.

The eggs of the pickle worm hatch in from 3½ to 4 days. During normal July and August weather the larvae require from 12 to 16 days for development. The rate of development for the 5 instars is 2½ days for the first, 2 days for the second, 2 days for the third, 2½ days for the fourth, and 5 days for the fifth, an average from hatching to pupation of about 14 days. The average life cycle was found to be 27 days.

"A full fourth generation occurs in North Carolina, but after the first one the generations are hopelessly mixed and overlapping. With sufficient food supply and warm October weather a fifth generation very probably occurs. Around Raleigh pickle worm moths continue to emerge until the latter part of October, but seldom later.

"The pickle worm does not have any important parasitic enemies in North Carolina, judging by the last 2 seasons’ work by the writer. Out of the hundreds of worms collected from the field and bred to maturity no true parasites have been reared with the exception of *Chalcis ovata*, and only one of these has been secured. . . . Predaceous insects kill a small percentage of pickle worms.
In fields about Raleigh the tiger beetle, *Calosoma calidum*, and several ground beetles, such as the common black form, *Harpalus caliginosus*, as well as bombardier beetles of the genus *Brachinus*, are quite numerous and doubtless prey upon the pickle worm. A predaceous larva which has been identified as *Chauliognathus pennsylvanicus* has been found in large numbers and is an active enemy of the pickle worm.

The author finds that a large proportion of the annual loss due to this pest may be prevented by growing summer squash as a trap crop, by destroying badly infested vines and fruit, and by general clean culture and deep plowing. Poison sprays are of little, if any, value against this pest.

The eggs of the melon worm hatch in warm weather in from 3½ to 4 days. The length of the larval stage was found to be from 13 to 16 days, the pupal stage from 7 to 11 days. The average life cycle proved to be 27½ days during August and September. Three generations occur in North Carolina, the first appearing in June or July, the second during the first part of August, and the last about the middle of September. During September and October, 1909, 2 parasites, *Amempherces* sp. and *Limicerus* sp., were frequently bred from the melon-worm pupae. *Chaleis ovata* was also reared from the pupa during the same year. The only remedial measures of value against melon worms consist of possible poisoning for those that eat the foliage, and the use of summer squash to help protect the more valuable crops.

Bibliographies are appended to the account.

The apple-tree tent-caterpillar (*Malacosoma americana*), A. F. Conradi (*South Carolina Sta. Bul. 158*, pp. 3-8, *fig. 1*).—This is an introductory report of investigations of the biology of this pest that are now in progress at Clemson, S. C.

"The eggs are deposited during the last week of May and first week of June in masses forming a belt around the small branches. They hatch during the last week of February and the first week of March the following year. The caterpillars spin a tent and use it for headquarters. They become full grown about April 27, when they discontinue social life and scatter to find some sheltered spot for pupation. The adult moths emerge from May 12 to 18, and lay eggs for the generation for the following year.

*Potato moth* at Patna, E. J. Woodhouse and A. P. Chowdhury (*Dept. Agr. Bengal, Quart. Jour. 4* (1911), No. 4, pp. 188-192, *pls. 3*).—As a protection against *Phthorimaea operculella*, an account of which by H. M. Lefroy has been previously noted (E. S. R., 24, p. 560), the authors recommend that potatoes be stored in dry sand.

Notes on the life history and habits of *Pegomya brassicae*, W. J. Schoene (*Jour. Econ. Ent., 4* (1911), No. 2, pp. 210-216, *pl. 1, fig. 1*).—These notes include observations on the oviposition of the first brood, the number of days from egg deposition to appearance of adults, larval stages and number of days required for the larva to mature, and aerial habits of larvae, together with the effect of plowing on pupae.

It was found that in some fields a large percentage of the larvae work in the top part of the plant during September and October. It is thought probable that the adults are attracted to the "sprouts" because of the tender growth. Rough estimations based on the examination of from 50 to 100 plants in each of a number of fields indicate from 300 to 1,500 maggots per acre. Attention is called to the fact that this aerial habit of the larva can be taken advantage of in combating the pest by removing the crop remnants. Observations of plowed and unplowed seed beds showed that only about 27 per cent as many flies emerged from the former as from the latter.
Oriental species of Stomoxys, Sophia L. M. Summers (Ann. and Mag. Nat. Hist., 8, ser., 8 (1911), No. 44, pp. 235-240, figs. 5).—A table is given for the separation of 10 Oriental species of Stomoxys. One species, Stomoxys pratii, is described as new to science.

A fruit fly menace, O. E. Bremner (Cal. State Com. Hort. [Circ.], 1911, pp. 3-7, fig. 1).—This paper calls attention to the danger of introducing the Morelos orange maggot (Trypetta laevis) from Mexico, and the melon fly (Dacus cucurbita) and Mediterranean fruit fly (Ceratitis capitata) from the Hawaiian Islands, into California.

House flies, L. O. Howard (U. S. Dept. Agr., Farmers' Bul. 459, pp. 16, figs. 9).—This account is modified and amplified from Circular 71, previously noted (E. S. R., 17, p. 1004).

The typhoid fly on the Minnesota Iron Range, F. L. Washburn (Pop. Sci. Add., 79 (1911), No. 2, pp. 137-150, figs. 10).—An illustrated address delivered at the annual meeting of the Entomological Society of America, on December 28, 1910.

The fleas common on rats in different parts of the world and the readiness with which they bite man, Harriette Chick and C. J. Martin (Jour. Hyg. [Cambridge], (1911), No. 1, pp. 122-136, pl. 1).—"Ceratophyllum fasciatus, like Xenopsylla cheopis, readily bites man. Out of 517 experiments 308 fed, or 59 per cent were positive. In 101 experiments, under identical circumstances with a rat, 59, or 58.4 per cent, of the fleas fed. The experiments with C. fasciatus were made upon 8 persons and evidence was obtained of preference on the part of the insects for particular individuals. One hundred and eleven experiments were made with 46 specimens of Ctenopsylla musculi; only 4 fed, or 8.6 per cent, whereas 9 out of 11 fed on a mouse. Sixty-eight specimens of Ctenophilthylus agyrtes were tried, in some cases upon 3 persons. None fed, whereas 11 out of 19 of the same fleas fed on a rat under identical conditions."

A bibliography of 32 titles is appended.

Life history of the rice weevil (Calandra oryza) in Alabama, W. E. Hinds and W. F. Turner (Jour. Econ. Ent., 4 (1911), No. 2, pp. 230-236, pl. 1).—The authors find that the period of oviposition is nearly as long as the life of the female, beginning within a few days of her emergence from the grain. The maximum oviposition period observed was 110 days but this female was still active at the time of writing. During this period 417 eggs were deposited.

Hatching occurs in an average of 3 days from deposition of the egg with a mean temperature between 60 and 65° F. "The first larval stage requires about 3 days, the second 4 days, and the third 9 days on the average, with a mean temperature between 60 and 65° F. There is then a distinct prepupal stage in which the forming pupa is plainly visible through the unshed larval skin, lasting usually for one day. The entire larval stage, therefore, requires between 16 and 17 days on the average, with a common range between 15 and 19 days under usual temperature conditions." There seems to be considerable variation in the length of the pupal stage at the same period, with the average at about 6 days and the range between 3 and 9 days.

The breeding of weevils continues more or less steadily throughout the winter provided the temperature remains sufficiently high. "At an average temperature of about 63°, development from oviposition to the emergence of the adult may take place in about 32 days. The general average, however, is rather longer than this, and for the first field generation appears to be about 6 weeks and for the second field generation between 7 and 8 weeks. This is between about the first week of August and the last of October."
Many weevils hibernate in the field, having been found moving in the fields as early as February in Texas after a mild winter and as early as January 30 in Alabama. The average duration of the life cycle during August and September is between 7 and 8 weeks.

The authors found evidence of the occurrence of parthenogenesis.

The cotton square-weevil of Peru and its bearing on the boll weevil problem in North America, C. H. T. Townsend (Jour. Econ. Ent., 4 (1911), No. 2, pp. 241-248).—The author has found that the serious affection of cotton in Peru, known for the last 45 years as the "hileo," is apparently due to a small weevil, Anthonomus vestitus, or n. sp., the habits of which are similar to those of the boll weevil. Since this weevil does not attack the bolls, due to the fact that in Peru squares are always present, the name cotton square-weevil is given to it.

It is estimated that in Peru the "hileo" has resulted in more damage to the cotton crop than all other causes combined. Numerous weevils were reared from both dried and green squares, both hanging and fallen. The weevil was found to occur commonly and generally, but in limited numbers, throughout the cotton districts of Piura Department during September and October; further investigation shows that it probably occurs throughout the cotton regions of western Peru and Ecuador. It was ascertained that about 23 days elapse from egg to adult during September and October. Search during September and October for weevils feeding and ovipositing in the squares, gave an average everywhere in the cotton region of Piura Department of one weevil to about 20 or 25 squares.

Two species of parasites, probably Bracon sp. and Urosigalaphus sp., have been reared in considerable numbers from the weevil larvae in the infested squares. The percentage of parasitism has not yet been determined, but the indications so far are in the neighborhood of 30 per cent and perhaps very much more. In spite of an extended search including a 3 weeks' overland trip into the Andes of southern Ecuador, the author has failed to find the square-weevil on any plant other than cotton.

Bee keeping in Maryland (Maryland Sta. Bul. 154, pp. 227-269, figs. 26).—This bulletin consists of 2 parts. The first, which is by T. B. Symons (pp. 227-236), deals with the status of bee keeping in the State; the second, by A. H. McCray, of the Bureau of Entomology of this Department (pp. 237-269), discusses the management of bees. A bibliography is appended.

A method of securing the fertilization of clover by means of bumblebees, in experiments with Bruchophagus funebris, F. L. Washburn (Jour. Econ. Ent., 4 (1911), No. 2, pp. 149, 151).—The technique is described.

A new species of Coccophagus with a table of the host relations of those species of the genus known to the writer, L. O. Howard (Jour. Econ. Ent., 4 (1911), No. 2, pp. 276, 277).—C. albicosta reared from Physokermes insignicola from Lampoc. Calif., is described as new.

The larch sawfly in Minnesota, A. G. Ruggles (Jour. Econ. Ent., 4 (1911), No. 2, pp. 171, 172).—The presence of this insect in Minnesota was first noted in August, 1909, though from the dead and dying tamaracks observed it is thought that the pest must have been at work during the 2 or 3 years preceding. The areas of infestation in the State are one at Itaska Park, a second at Cloquet, and a third near Ely. A hymenopterous parasite determined as Diglochis sp. was reared in large numbers, the author estimating that from 10 to 15 per cent of the cocoons were parasitized. In one small area as many as 5 per cent of the 1909 cocoons examined were found to be affected by a fungus disease.
A synonymic index-catalogue of spiders of North, Central and South America with all adjacent islands, Greenland, Bermuda, West Indies, Terra del Fuego, Galapagos, etc., A. Petrunkevitch (Bul. Amer. Mus. Nat. Hist., 29 (1911), pp. V+791).—This work is divided into 3 parts. Part 1 (pp. 11-39) consists of a bibliography of 533 titles; part 2 (pp. 41-720) of the catalogue proper, with complete synonymy, references to publications, years, volumes, pages, and figures, as well as to the localities indicated by different authors; and part 3 (pp. 721-790) of an alphabetic list of synonyms.

A handbook of the tsetse flies (genus Glossina). E. E. Austen (London, 1911, pp. X+110, pls. 10, figs. 2); rev. in Sleeping Sickness Bur. (London) Bul., 3 (1911), No. 27, pp. 223-225).—This handbook replaces the monograph by the author, previously noted (E. S. R., 15, p. 621), now out of print, and brings the subject up to date. Fourteen species are described of which 2 are new to science, namely, G. fuscipennis from the northeast of Congo Free State, and G. medicorum from West Africa.

A summary of its bionomics, so far as known, is given under the heading of each species, G. palpalis excepted.

Supplemental studies of trypanosomes, F. K. Kleine and M. Taute (Arb. K. Gesundheitsamt., 31 (1911), No. 2, pp. 321-376, pls. 5, figs. 5; abs. in Sleeping Sickness Bur. (London) Bul., 3 (1911), No. 2, pp. 165-175).—Investigations of the biology of trypanosomes and tsetse flies and the manner of transmission of the former, conducted in continuation of those by Koch, Beck, and Kleine, previously noted (E. S. R., 22, p. 684), are reported.

A bibliography of 61 titles is appended.

Spraying of woodland and shade trees, L. H. Worthley (Jour. Econ. Ent., 4 (1911), No. 2, pp. 188-193, pls. 3).—The data here presented are based on the experiments and experience of the gipsy-moth commission in Massachusetts.

Spraying apparatus for scale insects, E. L. Worsham (Jour. Econ. Ent., 4 (1911), No. 2, pp. 193-199).—The author considers apparatus and accessories, particularly with reference to their use in controlling the Coccide.

The California insecticide law, C. W. Woodworth (California Stu. Circ., 65, pp. 23).—The text of the California insecticide act of 1911 is here presented and discussed. This law requires manufacturers, importers, and dealers in insecticides and fungicides to obtain, on or before the first day of July of each year, beginning in 1911, a certificate of registration authorizing the sale of insecticides in the State. Insecticides and fungicides must be labeled to show (1) the name, brand, and trade-mark if there be any, (2) the name and address of the manufacturer, importer, or dealer, (3) the place of manufacture, (4) the chemical analysis, and (5) the registry number. The rules and regulations adopted by the United States Government for the enforcement of the federal insecticide act of 1910, also presented, are to be followed in holding private hearings.

Directions are given for the labeling of the various insecticides and fungicides.

Insect powder (U. S. Dept. Agr., Insecticide Decision 1, pp. 3).—The Insecticide and Fungicide Board here rules that the term "insect powder" when used without qualification means an insecticide made from the powdered flower heads of certain species of chrysanthemums, namely, Chrysanthemum (Pyrethrum) cinerariaefolium, C. (Pyrethrum) roseum, and C. marshallii (Pyrethrum coronum). In designating a mixture of powdered flowers and stems, the term "insect powder" may be used, provided this is immediately qualified by word or phrase so as to indicate clearly the nature of the article. Investigations to determine the precise value of the powdered stems are stated to be under way. The terms "Pyrethrum" and "Pyrethrum powder" are, when applied to insecticides, deemed synonymous with "insect powder."
California white wheats, G. W. Shaw and A. J. Gaumnitz (California Sta. \textit{Bul.} 212, pp. 315–321, figs. 18, \textit{docs.} 3).—The results are given of an extended series of investigations on the physical characteristics, chemical composition, and milling and baking qualities of white wheats grown in California, more particularly White Australian, Binestem, Little Club, Propo, and Sonora wheats.

Measurements of the thickness of the bran indicated considerable variation in different parts of the same kernel, “and that the bran from kernels on the center of the head is thicker than in kernels from either end.”

The California white wheats, according to the data presented, have a low nitrogen and protein content, the larger normal kernels usually carrying a higher percentage of nitrogen than the smaller kernels of the same type. The wheats are relatively high in fiber and low in ash and ether extract as compared with the hard winter wheats.

The wheat crop of 1905 contained uniformly a lower nitrogen content than did the crop of 1904.

The overlap of gluten nitrogen in the salt soluble extract is represented in the case of white wheat meals by the factor 0.15 per cent; in the case of flour by the factor 0.22 per cent. In the experimental work the polariscopic method for the determination of gliadin proved very reliable, while the mechanical separation of gluten in the case of this class of wheats was very unsatisfactory. The California white wheats contain a larger proportion of their total protein in the form of gluten than do most other wheats, and the gliadin number of these wheats is much lower than for those of the Middle West.

These California wheats ordinarily produce a very white flour which bakes darker than the tinted flours from winter wheats. The water absorption of these wheats is relatively low. The white wheat flours absorb about 52 per cent, and the hard spring wheat flours about 58 per cent.

According to the baking tests, loaves showing the greater loss in baking, other things being equal, are the lighter and whiter. Glutens from white wheat flours are not tenacious in proportion to their gliadin content. When hydrolyzed the glutens of these white wheats gave higher values than other types of wheat, and in general the white wheat glutens were inferior in quality and dull in color.

Wheat investigations—milling, baking, and chemical tests, E. F. Ladd and C. H. Bailey (North Dakota Sta. \textit{Bul.} 93, pp. 204–253, \textit{docs.} 5).—The yield, quality, and character of North Dakota wheats were studied in continuation of previous work (E. S. R., 24, p. 760), and in cooperation with the Office of Grain Standardization of this Department.

The average quality of the hard spring wheat of the 1910 crop was found to be superior, both in the yield of flour and in the gluten content and baking strength of flour, to the 1908 and 1909 crops, while the average quality of the 1910 durum wheats was somewhat inferior to that of the two preceding crops. The bearded spring or Velvet Chaff wheats, when dry and well cured, compared very favorably with other hard spring wheats raised in other localities.

Milling tests with a small two-stand experimental mill showed that, when properly handled, it will produce flours which indicate relative baking qualities, but does not give accurate quantitative milling yields.

“The durum wheats do not necessarily contain more crude protein and gluten than the hard spring wheats, when raised under the same conditions. The composition and feeding value of the by-products or feeds, as a usual thing, bear a distinct relation to the composition of the wheats from which
produced, being higher in protein when produced from high protein wheats, and lower in protein when low protein wheats are used. The moisture content of flours and feeds depends to a large extent on the moisture content of the wheat before tempering, when the same method of milling is followed in all cases. With wheats of the same general type the loss in milling due to evaporation runs approximately parallel to and increases with the moisture content of the wheat before tempering, when the same method of milling is employed."

**Milling experiments.** A. E. V. Richardson and G. H. Stevens (*Jour. Dept. Agr. So. Aust.* 14 (1910), No. 5, pp. 359–365; fig. 1; 14 (1911), Nos. 6, pp. 560–568, figs. 3, dpm. 1; 7, pp. 651–657, figs. 2).—Studies of the milling and baking qualities of high-grade and low-grade wheats showed, in the authors’ opinion, that on the whole the wheats above the standard were of greater monetary value than samples of the same variety below the standard, as they gave a higher yield of flour of higher quality.

A comparative study was made of the characteristics of wheat harvested at the Parafield experimental farm in 1900, and the results are also reported of a study of the absorption of moisture in conditioning wheat, that is, moistening before grinding. Analytical results showed that “with reasonable care conditioning may be carried out so that practically all the moisture absorbed by the grain will be contained in the external shell, and not interfere in any way with the flour.”

With regard to the character of break flour, tests with a number of varieties showed that, “providing a reasonable amount of break flour is produced, and that the breaking process is conducted in a gentle manner with a view to narrowing down the amount of break flour produced, the break flour is invariably superior in color to the bulk flour.

“The superiority of color, however, is not associated with a corresponding superiority in strength. As a matter of fact, the break flours have, without exception, given lower strength than the bulk flours.”

In general, the gluten content of the break flour was greater than in the bulk flour, while the break flour was “undoubtedly weaker than the reduction flour.”

From experiments on blending it was noted that “the strength of the mixtures obtained from the blending of the flours is considerably above the strength of the corresponding mixtures obtained in blending wheats.”

The authors believe that the probable nitrogen and gluten content of any mixture of either wheat or flour may be calculated with considerable accuracy, provided the nitrogen and gluten content of the component parts of the mixture is known.

“The probable strength of a given mixture, either of wheat or flour, can not, however, be determined by simple calculation, but the... [figures reported] tend to prove that if a weak or medium strong wheat be mixed with a strong flour wheat considerable improvement in strength of the two former takes place, and the improvement, especially with blends of flour, is considerably in advance of what might be expected from a knowledge of the strength of the originals of the blend.”

**Analysis of the products of hydrolysis of wheat gliadin.** T. B. Osborne and H. H. Guest (*Jour. Biol. Chem.* 9 (1911), No. 5, pp. 425–438).—Studies were undertaken to reduce the discrepancy between the amount of hydrolytic cleavage products recoverable from wheat gliadin and the theoretical amount.

According to the authors, “72.46 per cent of the total nitrogen was recovered in definite form, [and], in fact 75.7 per cent are shown by the complete analysis to be accounted for. This difference is largely due to the decomposition of the bases, tryptophane, and other amino acids during the distillation.”
On the dietetic value of the so-called “standard” bread, A. Smetham (Roy. Lancashire Agr. Soc. Jour., 1911, pp. 19-38).—From a summary of data the author concludes that the claims of superiority made for whole wheat bread are not substantiated. Particular attention is paid to the importance of mineral constituents, and the author discusses at length the need for a supply of lime for combining with phosphoric acid.

**Bakers and baking in Massachusetts, A. W. Brayley** (Boston, 1909, pp. XX+336, figs. 157).—As the subtitle states, this volume deals with flour, the baking supply, and kindred interests from colonial times to the present day, as well as with the baking trade. A large amount of statistical and other data is included on bread and bread making, bakers' equipment and machinery, the baked bean industry, and other similar topics.

**Rice as a foodstuff, II. Acon and F. Hocson** (Biochem. Ztschr., 32 (1911), No. 3-4, pp. 189-203).—Experimental studies are reported on the balance of income and outgo of nitrogen on a diet of rice supplemented by other foods, chiefly of vegetable origin, including such materials as bananas, rice polish, and phytin. Analyses of a large number of samples showed that relatively more phosphorus than nitrogen was lost by polishing rice. The unpolished rice contained on an average from 0.7 to 0.8 per cent P₂O₅, undermilled rice from 0.4 to 0.6 per cent, and overmilled rice from 0.15 to 0.4 per cent.

The authors conclude that an exclusive rice diet will not supply protein enough to meet man's demands, and that therefore it must be supplemented by vegetable, or better, animal foods rich in protein. Such a mixed diet is satisfactory from an hygienic standpoint, provided the rice has not lost too much phosphorus by overmilling or polishing. From their experimental studies they conclude further that, for a man weighing 50 kg., a diet made up of rice supplemented by vegetable foods must contain at least 75 gm. protein in order to meet hygienic requirements, and that a diet of rice supplemented by fish or meat must contain at least 65 gm., of which at least \( \frac{1}{4} \) is supplied by animal foods.

The importance of rice in the Orient and other similar questions are considered.

Studies on chicken fat (U. S. Dept. Agr., Bur. Chem. Circ. 75, pp. 11).—Two studies are reported.

The occurrence and permanence of lipase in the fat of the common fowl (Gallus domesticus), Mary E. Pennington and J. S. Hepburn (pp. 1-7).—The following conclusions were reached from the experimental work reported:

"Lipase occurs in the crude fat of chickens. The fat of the fowl immediately after killing shows almost no lipolytic activity. It is therefore probable that the lipase during life exists in its zymogenic form. As the chicken ages after death, the enzym becomes active and the acidity of the fat increases. These changes occur less rapidly at temperatures below freezing than above the freezing point. Lipase can resist prolonged freezing for as long a period as 89 months. From the experiments cited it would appear that the post-mortem hydrolysis of chicken fat depends chiefly upon enzym action."

The oxidation of chicken fat by means of hydrogen peroxid, J. S. Hepburn (pp. 8-11).—The influence of oxidation by means of hydrogen peroxid upon the chemical constants of chicken fat and on stearic and oleic acids was studied. The fat was obtained from birds of known history, all the samples with two exceptions being western birds at various stages of their marketing.

A comparison of values before and after oxidation showed that the acidity of chicken fat always increased, while the iodin number usually decreased, although sometimes the reverse was noted. "The saponification number and the Hohner number almost invariably increased simultaneously, hence dilute
hydrogen peroxid at the temperature of the water bath produced in chicken fat the same chemical change that occurs in that fat in situ during prolonged freezing.

"Stearic and oleic acids were also oxidized with hydrogen peroxid. The saponification number of the acids decreased. This change is similar to that undergone by the fat of chickens kept hard frozen for a period of 4 months, at the end of which time both the saponification number and the Helmer number were lower than in the fat of fresh birds. . . .

"The changes in the fat of chickens during prolonged freezing are similar to the changes called forth by oxidation of the fat with hydrogen peroxid. The Helmer number and the saponification number increase simultaneously, and aldehydes are formed. The increase in saponification number may, therefore, be ascribed to the formation of slightly lower homologues of the fatty acids of fresh chicken fat, while the increase in Helmer number is doubtless due to the formation of aldehydes and ketones of high carbon content. These changes in the chicken fat in situ are probably produced by the action of enzymes."

Studies of cottage cheese, R. Windisch (Ztlscr. Untersuch. Nahr. u. Genussm., 21 (1911), No. 19, pp. 613–615).—Analyses of a number of samples are reported.

[The use of whale flesh as food], R. C. Andrews (Nat. Geogr. Mag., 22 (1911), No. 5, pp. 411–412, figs. 34; abs. in Sci. Amer., 105 (1911), No. 3, pp. 56, 57, figs. 4).—Information is summarized regarding the present use of whale meat as food, particularly in Japan, and suggestions are made regarding the possibilities of its general consumption.

Ptomaines in canned fish and crustacea, A. Desgrez and F. Gaius (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 13, pp. 893–895).—Following usual methods, the authors determined the amount of ptomaines in 18 samples of canned goods, finding from 0.2 to 0.6 gm. per kilogram. The results are discussed with reference to methods of preparing and handling foods. The authors found that the bases isolated were relatively not very toxic, but apparently their nature was not determined.

Ripe and unripe bananas, R. Reich (Ztschr. Untersuch. Nahr. u. Genussm., 22 (1911), No. 4, pp. 208–226).—Analyses are reported of dried ripe bananas of different sorts, unripe bananas, banana flour, skins from ripe and unripe bananas, and fresh bananas of different sorts, the data being discussed in comparison with similar results of other investigators.

The conclusion is reached that in the case of bananas which are shipped green and then allowed to ripen the transformation of starch into sugar takes place normally. The inversion of saccharose, however, proceeds slowly under such conditions, full inversion being noted only under favorable temperature conditions. It appears further that bananas in which the saccharose content is higher than the invert sugar are to be regarded as "unripe." The flavor is flat, and there is little or no aroma.

In general the Surinam, Jamaica, and Canary Island bananas had essentially the same composition, the crude fiber, acid, and ash content of the 3 sorts being practically the same. The nitrogen content of the Canary Island bananas, however, was somewhat higher than that of the other 2 sorts, which are practically alike in this respect.

Particular attention is paid to the discussion of the ash content of bananas and to the relative cost of the fresh and dried fruit.

The composition of tomato catsups, E. W. Duckwall (Canner and Dried Fruit Packer, 33 (1911), No. 2, pp. 34, 36).—From a summary and discussion of data the author concludes that the ratio of insoluble to total solids, which practically means the ratio of tomato solids to total solids, is the most important
of the analytical data usually recorded in the examination of such goods. "This ratio should never be less than 1:7 in good catsup, and if a standard is ever promulgated it is very likely that it will be largely based upon (this ratio)."

**Dirt in food.** Emily L. Dove (Jour. Roy. Sanit. Inst., 32 (1911), No. 6, pp. 321-335, agms. 2).—Determination are reported of the amount of dirt on cress, parsley, fresh and dried fruits, in soda water, milk, and other food materials, and information is given regarding the bacteria, inorganic material, and organic material of which the "dirt" was composed.

As regards the effect on digestion of dirt in food, the author found in artificial digestion experiments that clean flour under the same conditions was more thoroughly digested in a given time than a like quantity of flour which had dust mixed with it. Feeding experiments with guinea pigs on clean and on unwashed and unsterilized food did not show any differences which would warrant deductions.

Though the study was made with foods marketed under conditions prevailing in London, the results are of general interest.

A discussion follows the paper.

**Food chemistry and food control.** A. Kraus (Nahrungsmittelchemie und Nahrungsmittelkontrolle. Leipsic, 1911, pp. X+196).—This handbook, designed for the use of students and others interested in the subject, has to do particularly with foods in their commercial and technical relations.

**Notices of judgment** (U. S. Dept. Agr., Notices of Judgment 988, p. 1; 989, pp. 2; 991-994, p. 1 each; 996-999, p. 1 each; 1000, pp. 11; 1001, p. 1; 1003-1015, p. 1 each; 1016, pp. 2; 1017, p. 1; 1019, pp. 2; 1020, pp. 3; 1021-1022, p. 1 each; 1023, pp. 2; 1024-1025, p. 1 each; 1026, pp. 2; 1027, pp. 3; 1029, pp. 2; 1030-1032, p. 1 each; 1034, p. 1).—The following subjects are included: The misbranding of humbug oil, "Eq. nutrine, whole egg substitute," "powd. Alex. senna," coffee, Dr. Moffett’s teethina, champagne, rheumatic cure, "Cerrodanie cap-sues," ginger ale, and "royal lithia water"; the adulteration of desiccated eggs, tomato catsup, tomato pulp, sodic alumimin sulphate, tomato paste, Cayenne pepper, shad, and turpentine; the adulteration and misbranding of a food product ("chocolate cremolin"), turmeric, olive oil, tragacanth, "brace-up tomato tonic," tomato catsup, vinegar, "gr’d Alex. senna," ground kamala, powdered colocynth, maple sugar, lemon extract and vanilla extract, and rice; the alleged adulteration of frozen egg product; the alleged adulteration and misbranding of "soda water sirup cola"; bond forfeituer (wine); and bond forfeituer (coffee).

**Special food analyses, 1911.** R. E. Rose and A. M. Henry (Fla. Quart. Bul. Agr. Dept., 21 (1911), No. 3, pp. 110-118).—The results are given of the examination of a large number of samples of beverages, jams, and miscellaneous food products.

**[Food inspection and similar work],** J. G. Winkel et al. (Bier. Rpt. Minn. State Dairy and Food Comr., 13 (1909-10), pp. 288, pls. 10).—Of 6,026 samples of foods, beverages, leads, and paints examined, 1,997 were declared illegal. The usual reports are included.

**[Living conditions in Samoa],** E. Deeken (Umschau, 15 (1911), No. 35, pp. 713-716).—Considerable information is summarized regarding the food habits and living conditions of foreign residents in Samoa.
The food of the Tasmanian aborigines, F. Noetling (Papers and Proc. Roy. Soc. Tasmania, 1910, pp. 279–305).—A large amount of data is summarized and discussed regarding the foods and food habits of the now extinct aboriginal inhabitants of Tasmania. As the author points out, there is a general agreement of opinion that the diet was very largely of animal origin, shellfish, game, eggs, etc., being supplemented by a limited supply of vegetable foods.

Free restaurants for nursing mothers (Restaurants Gratuits des Mères Nourrices. Paris, [1907], pp. 16, figs. 2).—An account is given of the establishment of restaurants for supplying free food to nursing mothers in Paris and the success which has attended the enterprise.

Household chemistry, J. F. Snell (Montreal, 1911, pp. 65).—In addition to a discussion of the elementary principles of chemistry which are of special interest in this connection, the topics considered are acids, bases, and salts, and their relation to cleaning processes; fats and soaps; and food constituents and their composition, digestion, identification, and chemical characteristics. Appended to the text are a number of tables showing the composition of common food materials and other similar data. The present publication, which the author regards as preliminary to a more extended treatise, brings together in concise form a great deal of interesting material of use to students.

General treatise on nutrition, G. Leben (Allgemeine Nahrungsmittelkunde, Berlin, 1911, pp. XI+523, figs. 57).—This handbook contains chapters on meat, fish, game, fruits, vegetables, and other foods, and on beverages.

Nutrition and growth, I. H. Aron (Philippine Jour. Sci., B. Med. Sci., 6 (1911), No. 1, pp. 1–52, pls. 5, 9, 97, 99–101, 102–105).—Experimental studies of dogs are reported, together with the results of observations on nursing children.

The author concludes that “a growing animal which receives only sufficient food to keep its body weight constant, or to allow a slight increase, is in a condition of severe starvation. If by a restriction of food the increase in weight is inhibited, the skeleton grows at the expense of other parts of the body, especially of the flesh. Most of the organs retain their weight and size, while the brain grows to reach its normal weight. The composition of the body—when at a constant weight—undergoes remarkable changes. Fat is consumed more or less entirely, the quantity of protein, especially of the muscles but not of the organs, is diminished and a great proportion of the body tissues is replaced by water; thus, this water and the increase of the skeleton together replace the body materials lost. The caloric value of 1 gm. body weight of an animal which has undergone such a process to its extreme limit may amount to only one-third of the normal value.

“ ‘It is possible by supplying suitable amounts of food to maintain a dog in an emaciated condition, apparently in good health, and at the weight of a puppy, for nearly 1 year, while its weight at the end of the year should be 3 times as great. If such an animal is therupon fed amply, it fattens and rounds out, but does not reach the size of a control animal which from the beginning has been normally fed. It is unable to make good the growth suspended by the long restriction of food.

“The ‘growth’ principally depends on the tendency to grow possessed by the skeleton. The skeleton loses its capability of growing in more advanced age regardless of the size which the animal has reached.”

See also a previous note (E. S. R., 24, p. 765).

The digestibility of white of egg as influenced by the temperature at which it is coagulated, P. Frank (Jour. Biol. Chem., 9 (1911), No. 6, pp. 463–470, 97, 98–100).—Some of the conclusions drawn from experimental work are quoted.
"The progress of the hydrochloric acid action and the total digestion is most rapid in the albumin not heated beyond 75° C. . . .

"The rate of digestion seems to progress more evenly with the hydrochloric acid action in the albumin heated up to 75° than it does in the others. . . .

"The progress of the hydrochloric acid action and the digestion while proportionately greater the longer the period of digestion, diminishes relatively as digestion continues. . . .

"It is quite evident, from the results discussed in this paper, that the Mett. tube method of standardizing ferments is an unreliable one unless special precautions be taken."

The metabolism of fruit acids in warm weather, B. F. DUCKWALL (Canner and Dried Fruit Packer, 33 (1911), No. 2, pp. 35, 40).—A summary of data regarding the metabolism of fruit acids and related topics.

Colloidal-chemical analysis of the phenomena of absorption and secretion—absorption in the intestinal tract, M. H. FISCHER (Kolloidchem. Beihefte, 2 (1911), No. 8-9, pp. 304-342).—An extended digest of data and discussion of digestion from the standpoint of colloidal chemistry.

Muscular work and protein metabolism, A. PUGLIESE (Biochem. Ztschr., 33 (1911), No. 1-3, pp. 16-29).—From studies of the nitrogen content and its distribution in muscles the author concludes that metabolic changes take place either not at all or in very limited degree in muscular work. Practically all the substances withdrawn from working muscles are substances widely distributed in the body and are not to be regarded as abnormal.

The human machine, A. BENNETT (New York, [1911], pp. 123).—In this volume the author discusses training the mental powers with a view to increased efficiency.

**ANIMAL PRODUCTION.**

The study of heredity, V. HAECKER (Allgemeine Vererbungslehre. Brunswick, 1911, pp. 16-392, pls. 4, figs. 135).—This is a general treatise on heredity based on results of recent investigations. The contents are grouped under the following headings: Historical introduction, morpho-biological foundations of the study of heredity, Weismann's theory of heredity and problem of the inheritance of acquired characters, experiments in hybridizing, and new morpho-biological theories of heredity.

A bibliography is appended to each chapter.

Introduction to the study of heredity, E. BAUR (Einführung in die Experimentelle Vererbungslehre. Berlin, 1911, pp. 293, pls. 9, figs. 80; rev. in Biol. Centbl., 31 (1911), No. 16-17, pp. 533, 544).—A systematic treatise on heredity from the modern standpoint, based mainly on investigations of recent years with both plants and animals by experimental methods.

A bibliography of 426 titles is appended.

Introduction to the science of heredity, R. GOEDSCHMIDT (Einführung in die Vererbungswissenschaft. Leipsic, 1911, pp. 16-502, figs. 161).—This is a course of 20 lectures on heredity based on recent investigations. A bibliography of over 500 references is appended.

A coefficient of individual prepotency for students of heredity, J. A. HARRIS (Amer. Nat., 45 (1911), No. 536, pp. 471-478).—A discussion of the conception of prepotency and methods of measuring individual prepotency. Certain biometric formulas used for other purposes are suggested as well adapted for measuring the desirability of the individual parents for breeding.

On the formation of correlation and contingency tables when the number of combinations is large, J. A. HARRIS (Amer. Nat., 45 (1911), No. 537, pp.
Experimental polyspermy as a means of studying the problem of fecundation. A. Brachet (Arch. Entwickl. Mech. Organ., 30 (1910), pt. 1, pp. 261-303, figs. 9; abs. in Zentralbl. Physiol., 21 (1911), No. 23, p. 1094).—The author has studied fecundation under abnormal conditions in Rana fusca for the purpose of gaining information on the underlying principles. When the sperm was concentrated many spermatozoa could enter the ovum, and if the number entering was small there were as many blastomeres as there were spermatozoa. The female nucleus united with the spermatozoa lying nearest to it. When the number of spermatozoa was large there was more or less union among them, forming groups and chains.

Results obtained thus far furnish further support to the view that the phenomenon of fecundation may be accounted for by forces lying entirely within the nucleus.

Artificial parthenogenesis of frog's eggs, E. Bataillon (Compt. Rend. Acad. Sci. [Paris], 150 (1910), No. 16, pp. 996-998; 152 (1911), No. 19, pp. 1271-1273; abs. in Jour. Roy. Micros. Soc. [London], 1910, No. 6, p. 796; 1911, No. 4, p. 554).—A minute puncture of the eggs of Rana fusca with a fine needle made of glass, platinum, or manganese apparently caused a change in the osmotic equilibrium, as many eggs underwent gastrulation and developed into free larvae. Segmentation was also induced by injecting into the eggs some mammalian blood, sperms, extract of spleen, carp blood, or extract of testis. The accelerating principle introduced need not be specific. The essential conditions are puncture and the introduction of some foreign cellular elements.

Number of chromosomes in Batrachians and in parthenogenetic embryos, A. Dehorne (Compt. Rend. Acad. Sci. [Paris], 150 (1910), No. 22, pp. 1451-1453; 152 (1911), No. 17, pp. 1123, 1124; abs. in Jour. Roy. Micros. Soc. [London], 1910, No. 6, p. 796; 1911, No. 4, p. 554).—The experiments of Bataillon (noted above) were repeated and only 6 chromosomes were found in the cells of embryos from 2 to 6 days old. The author finds that all the common Batrachians have 12 chromosomes, and not 2& as usually stated.

The state of the ovary in hybrids of the goldfinch and canary, A. Chapellier (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 9, pp. 328, 329, figs. 8; abs. in Jour. Roy. Micros. Soc. [London], 1911, No. 4, p. 555).—The author examined 25 hybrids between a male goldfinch and female canary, finding various degrees of fertility. In some cases the ovary was rudimentary and no ova were produced. In others, the eggs were small and sterile. Eggs were laid in only about one-fourth of the cases.

Studies in the experimental analysis of sex.—VI, On the cause of the fluctuations in growth of the fowl's comb, G. Smith (Quart. Jour. Micros. Sci. [London], n. ser., 57 (1911), No. 225, pp. 45-51, plvs. 4, figs. 5).—The results of this investigation, continuing previous studies (E. S. R., 23, p. 173), are summarized as follows:

"The rapid and marked increase in area of the hen's comb is proved both in adult and young hens to occur simultaneously with the periods of egg laying. This increase of the comb in the hen is due to a fatty infiltration of the central connective-tissue core of the comb; the decrease in the comb is due to the
abstraction of the fat. The cock's comb contains only small quantities of fat comparatively in the central core, the substance of the comb consisting principally of fibrous connective tissue. The cock's comb does not exhibit marked fluctuations like the hen. The increase in the comb is not accompanied by a rise in general body weight, though such a rise usually occurs some time before the increase and fat deposition occur. The explanation of the fatty infiltration of the comb is found in the fact that at the egg-laying periods the blood becomes charged with fatty material which is conveyed to the ovary for the formation of yolk, and that the excess of this fatty material is deposited in the comb. A close parallel is observed in the fat metabolism of the laying hen and of spider crabs parasitized by Sacculina."

Castration by X-rays, C. Regaud and T. Nogier (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 1, pp. 5-7; abs. in Jour. Roy. Micors. Soc. [London], 1911, No. 3, p. 37).—It was found possible to sterilize the testis of an adult cat by the use of X-rays and without lesion of the skin. Oviform cells survived the exposure, but they gradually diminished in number and the seminal epithelium remained sterile.

Sterilization by X-rays, T. Nogier and C. Regaud (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 2, pp. 50-52; abs. in Jour. Roy. Micors. Soc. [London], 1911, No. 3, pp. 347, 348).—Complete sterilization of the dog was obtained by means of the X-rays. As in the cat, there were some refractory oviform cells, but they were not able to repopulate the seminal epithelium. Sterilization was effected without radio-dermitis by taking precautions.

The geology and paleontology of the caves of Grimaldi, M. Boule (Les Grottes de Grimaldi.—Géologie et Paléontologie. Monaco, 1910, vol. 1, pt. 3, pp. 157-236, pls. 6; rev. in Nature [London], 87 (1911), No. 2178, pp. 112, 113, map 1).—This contains a full account of various animal bones recovered from the Baoussé-Raoussé caves at Mentone.

Of the ancestors of domesticated animals the Equidæ were represented by Equus asinus, E. caballus, E. caballus typicus, and E. robustus. Neither E. przewalskii nor the zebra appeared to have been present. Remains of Sus scrofa were abundant. In the Mentone neighborhood Bos primigenius made its appearance quite as early as Bison priscus, if not indeed earlier. Bos longifrons was absent. Rupicapra tragus was of a vigorous type, showing affinities to the chamois of the Alps and the Pyrenees. Capra ibex was represented by a large number of specimens, and is considered to be the ancestor of the Alpine goat of to-day.

Conclusions are confirmed that there was no sudden or complete break in the evolution or history of the fauna of western Europe from the Paleolithic to the Neolithic times, with but little natural organic evolution in the larger mammalia from the earliest Pleistocene to the present day, although some of the animals of the Pleistocene have disappeared through changes in climatic conditions or through the hand of man, while others have deteriorated in size and vigor as they have gradually come under the yoke. The horse, however, forms a notable exception, having improved in physique and gained in strength.

College live stock and judging competitions, C. S. Plumbe (Breeder's Gaz., 60 (1911), No. 7, pp. 240, 241, fig. 1).—This is a defense of student-judging contests, and a discussion of the merits and demerits of having colleges exhibit live stock at shows. It is stated that both arouse interest and are educational affairs, and are as reasonable and justifiable as student debates, orations, or other intellectual contests.

[The utilization of by-products of the vine as stock feeds], V. Vermeër and E. Dantony (In Utilisation des Sous-Produits de la Vigne et du Vin. 14867)—No. 8—11—6
EXPERIMENT STATION RECORD.

Paris, 1910, pp. 71-155, figs. 6).—A summary of information on the nutritive value and methods of preparing grape marc, prunings of vines, and other products of the grape for feeding live stock.

Filling the silo and the cost of silage, C. W. Pugsley (Hoard's Dairyman, 42 (1911), No. 28, p. 558).—Directions for filling the silo and estimates of the cost of filling are given.

The author found that where it took 18 acres to fill 2 silos of 110 tons each, with corn at 60 bu. per acre, the cost of ensilage per ton was $2.59. Experiences of others are cited to show the cost of filling to range from $1.95 to $2.75 a ton.

Concentrated feeding stuffs, C. S. Cathcart et al. (New Jersey Stas. Bul. 237, pp. 3-56).—This is the report of the eleventh inspection of concentrated feeding stuffs, and presents analyses of 630 samples of cotton-seed meal, cotton-seed feed, linseed meal, mustard seed oil cake meal, gluten feed, distillers' dried grains, dried brewers' grains, malt sprouts, molasses feed, alfalfa meal, barley feed, dried beet pulp, granulated milk, meat meal, beef scrap, by-products of corn, wheat, rye, oats, and buckwheat, and poultry and mixed feeds.

Notice of Judgment (U. S. Dept. Agr., Notice of Judgment 990, pp. 11).—This relates to the alleged misbranding of "Corno horse and mule feed."

The high price of meat in Germany according to a recent inquiry: Its causes and remedy by cooperative and other means (International Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Inst., 2 (1911), No. 5, pp. 242-265).—This inquiry was ordered by the Minister of Agriculture because of the high price of meat in 1910. The farmers have been accused of causing the increase, but inquiry showed that although the number of cattle, calves, and sheep was smaller in 1910 than in 1909, it was greater than the averages for the preceding 10 years, and that more pigs were marketed in 1910 than in any 5 of those years. The increase in price was due largely to the increase of consumption of meat per head of population. Suggestions are offered for increasing the home production of live stock.

Exports of Uruguay live-stock products, F. W. Goding (Daily Cons. and Trade Rpts. [U. S.], 14 (1911), No. 189, pp. 522, 523).—This contains statistics on the live stock industry and on the exports of live-stock products.

Margarin in skim milk for fattening calves, A. Chiesi (Indust. Latt. e Zootec., 9 (1911), No. 8, pp. 121, 122; abs. in International Inst. Agr. [Rome], Bul. Bur. Agr. Inst. and Plant Diseases, 2 (1911), No. 3, pp. 896, 897).—This is a report of a successful experiment in the use of margarin as a substitute for cream in skim milk. The average daily gain per head was 0.957 kg., and the price realized for the skim milk excluding cost of labor was 8.27 francs per quintal (about 1.5 cts. per quart).

Breeding and feeding sheep, J. W. Wilson (South Dakota Sta. Bul. 127, pp. 96-120, figs. 13).—This bulletin reports the result of 6 years' work, the object of which was to ascertain which of 6 breeds of sheep is the best to use on the western-bred ewe, both wool and mutton being considered.

In the fall of 1904 60 western Montana-bred yearling ewes were divided into 6 lots. These were compactly built Merino and Down grades and were quite uniform in size and conformation. Each of these lots was bred to an average pure bred ram of the following breeds: Cotswold, Hampshire, Oxford, Southdown, Shropshire, and Rambouillet. In 1905, the ewes previously bred to the Cotswold ram were bred to the Hampshire, the ewes bred to the Rambouillet ram were bred to the Cotswold, and so on for each lot, changing the breed of ram each year for each lot of ewes.

The ewes lambed in April and May each year, and the lambs were allowed to run with the ewes on blue grass pasture until early fall, when they were sepa-
rated and pastured on rape. On January 1 they were divided up as to breeds and fed until April 1 all they would eat of a mixture of 100 lbs. shelled corn, 100 lbs. oats, and 25 lbs. oil meal, with prairie hay. They were then shipped to Chicago and sold on their merits. The dressed weight percentage of each lot for the last 3 years of the experiment averaged as follows: Cotswold grades 52.4; Hampshire 53.4; Oxford 52.9; Southdown 53.1; Shropshire 53.2; and Rambouillet 54.2.

The lambs were sheared 2 weeks before marketing and the clip was shipped to Chicago, graded, and sold on its merits. The average yield in pounds of wool by breeds per head for the 6 years was for the Cotswold grades 7.9, Hampshire 6.7, Oxford 6.8, Southdown 5.6, Shropshire 6.4, and Rambouillet 7.

The number of lambs fed, the daily gains, amount of concentrates per pound gain, and value of wool per head are given in the following table:

Results in breeding sheep for wool and mutton.

Descriptive notes are given of each of the breeds represented. The death of 10 ewes during the winter of 1910 was attributed by the veterinarian of the station to lack of exercise and the long period of dry feeding. Notes by E. L. Moore of the station on the symptoms, treatment, and precautions to be used against tapeworms in sheep have been noted from another source (E. S. R., 15, p. 87).

The native breeds of swine in Croatia and Slavonia, ULMANSKY (Wiener Landw. Ztg., 61 (1911), No. 52, pp. 556, 597, figs. 3).—A description of the characteristics of the 3 principal native types of swine, (1) the Siska, (2) the Syrmie-Mangalica, and (3) the Turopolje. A brief account of the methods of swine breeding in Croatia and Slavonia is also given.

Cotton-seed meal feeding experiments with mules and horses, R. S. CURTIS (North Carolina Sta. Bul. 215, pp. 153-169).—The object of these experiments was to determine the possibility of using cotton-seed meal successfully in rations for work animals, the form and combination in which it may be best be fed, and the harmful effects, if any, resulting from its use. The concentrated feeds used were corn on the ear, shelled, and in the form of corn-and-cob meal, cotton-seed meal, and wheat bran. The roughage was mainly corn stover though at times oat hay, pea-vine hay, and mixed hay were fed. In calculating the financial statements the following prices per ton were used: Ear corn $20, shelled corn $25, corn-and-cob meal $20, cotton-seed meal $30, wheat bran $30.

In a preliminary test cotton-seed meal was fed as a supplementary feed to ear corn in quantities up to 1 1/2 lbs. daily to mules. The animals relished the cotton-seed meal only fairly well and its use in this manner is not recommended.

Five mules were fed shelled corn and cotton-seed meal for 6 months. The amount of cotton-seed meal consumed per mule during this period varied from 111.6 to 293.7 lbs. One mule was fed shelled corn only as a check. The mules performed as nearly the same amount of work daily as practicable. In each
case the cotton-seed meal ration cost slightly less, and, except in the case of one mule which lost in weight, the mules fed cotton-seed meal made more gains than the corn-fed mule. In this experiment it was impracticable to substitute more than 2 parts of cotton-seed meal for 1 part of shelled corn. Similar results were obtained in another experiment with these 6 mules, in which 1 mule in each team was fed the shelled corn ration, while each team mate was given the cotton-seed meal ration.

In an experiment with 6 mules in which 3 were fed a ration consisting of 7 parts of ear corn, 3 parts corn-and-cob meal, and 1 part cotton-seed meal, against ear corn only for the team mates, the cotton-seed meal was consumed much more readily than in the other experiments. However, the average amount fed daily was only about 1 lb. The cotton-seed meal rations cost slightly less per mule, and, with one exception, less per hour of work performed. In every case there was a gain in weight, but with one exception the corn-fed mules made greater gains.

In a test with 6 mules, corn-and-cob meal was fed in comparison with mixtures in different proportions of corn-and-cob meal, wheat bran, and cotton-seed meal. In each case the cost was more, though the amount of work performed and the gain was less on the cotton-seed meal rations.

The author states that in each case where cotton-seed meal was fed the coat of the animal became smoother and glossier than usual, that the spirit and endurance were not lessened, and that at the end of the experiment no harmful effects could be found as a result of feeding the meal. Farmers are advised not to feed draft animals cotton-seed meal to the extent of more than 10 or 15 per cent by weight of the total ration.

Feeding cotton-seed meal to draft animals, R. S. Curtis (North Carolina Sta. Bul. 216, pp. 177–186).—This is a popular discussion, based on the above experiments and other published matter relative to the use of cotton-seed meal for horses and mules, a digest of which is included. The more general use of cotton-seed meal for work animals by southern farmers is advocated from two viewpoints: First, its high protein content makes it a very desirable concentrate to balance the corn ration usually fed this class of stock; second, a large percentage of its fertilizing value is retained in the manure. The author states that only light yellow cotton-seed meal with a sharp, nutty odor should be used for horses and mules. Four cotton-seed meal rations are included, the quantities suggested being sufficient for medium weight draft animals doing moderate work.

Method for determining weight of parts of eggs, Maynie R. Curtis (Maine Sta. Bul. 191, pp. 93–112, figs. 3).—This bulletin presents the results of a study of methods by which an accurate determination of the weight of the several parts (albumin, yolk, and shell) of the hen’s egg might be made. “Such methods involve (a) the prevention of loss of weight by evaporation, pending the weighing of the egg, and (b) the accurate separation of the parts of the egg for weighing.”

In order to ascertain the amount of evaporation from eggs, 20 Barred Plymouth Rock eggs were brought to the laboratory soon after they were laid and divided into two groups of 10 eggs each. Each of the eggs of one group was sealed in a half-pint fruit jar in which a small amount of absorbent cotton had been placed to prevent breakage. The 10 eggs of the other group were placed in a wire basket on the laboratory table. The eggs were weighed each day for 4 days. The eggs kept in the open air lost daily from 0.04 gm. to 0.13 gm., with a mean of 0.0833 gm., while eggs kept in sealed jars lost from 0 to 0.04 gm., with a mean of 0.0228 gm. That is, keeping the eggs sealed in jars reduced the evaporation to one-fourth of that in the open air.

Before a study of the proportion of parts of eggs could be made it was necessary to determine an accurate method for separating these parts. It was found
that this was comparatively easy with boiled eggs. In this work the eggs were weighed fresh and dropped into boiling water, allowed to boil 20 minutes and cooled, and weighed again before separation. The eggs lost from 1 to 1.5 gm. each due to boiling and cooling. To test the loss in weight due to different methods of cooling boiled eggs, some were cooled in water, some in air, and some in sealed jars. Those cooled in the open air lost from 1.49 to 1.75 gm., with a mean of 1.578 gm.; those cooled in sealed jars lost from 1.27 to 1.79 gm., with a mean of 1.016 gm.; and those cooled under water lost from 0.91 to 1.33 gm., with a mean of 1.1425 gm. However, as a loss of more than 1 gm. was deemed too large to be overlooked in a quantitative study of the proportion of parts of eggs, a slight modification of the housewife's method of separating the parts of fresh eggs was devised. It is described as follows: "Break the egg near the center and allow the albumin to run into a receiving dish. Keep the yolk in one half of the shell. Then turn it into the empty half. The yolk is then dried on a filter paper. The shell is also dried on a filter. The yolk and shell are then weighed. The difference between the sum of their weights and the original weight of the unbroken egg gives the weight of albumin."

In an experiment in which 15 eggs were separated fresh and the parts weighed the averages were as follows: Entire egg 58.87 gm., albumin 35.39 gm., yolk 16.82 gm., shell, etc., 6.48 gm., percentage of error in weights 0.66. Similar data for 14 eggs separated after boiling are as follows: Entire egg fresh 54.52 gm., boiled 53.04 gm., albumin 30.61 gm., yolk 16.59 gm., shell, etc., 5.71 gm., percentage of error in weights 0.62.

Diagrams are included showing the relation between the size of the eggs and the loss of weight by evaporation in the open air and the relation between the weight of the whole egg and its parts in eggs separated fresh and after boiling. These diagrams show some positive correlation between the weight of the egg and (1) its loss in weight by evaporation and (2) its percentage of albumin, and a negative correlation between the weight of the egg and the percentage of yolk. No correlation was found between the weight of egg and the percentage of shell.

Illustrated album of pigeons, E. Schachtzabe (Illustriertes Prachtwerk sämtlicher Taubenrassen. Würzburg, [1911], pp. 14, pls. 100, figs. 7).—This contains descriptions and colored plates of all breeds of pigeons commonly kept in Germany.

DAIRY FARMING—DAIRYING.

Feeding experiments with cows and calves, J. Michels (North Carolina Sta. Bul. 213, pp. 89-97).—These experiments were undertaken to determine the relative efficiency of narrow and medium wide rations for milk production.

Eight cows from 3 to 6 weeks in lactation were fed 3 periods of 28 days each. In the first and third periods the feed consisted of 5 parts cotton-seed meal, 4 parts wheat bran, 3 parts corn meal, and 50 lbs. corn silage. The nutritive ratio of this ration was about 1:4. During the second period the ration was the same as the above, except that 2.5 lbs. of cotton-seed meal was replaced by 2.5 lbs. of corn meal, giving this ration a nutritive ratio of about 1:57. The results of this test indicate that the narrow ration produced 7.5 per cent more milk fat, and increased the fat test 0.24 per cent and the live weight 30 lbs. The milk yield was practically the same. This trial was duplicated with 5 cows, except that the narrow ration was fed during the first and third periods, and the medium ration during the second. The narrow ration produced 7.6 per cent more milk fat, increased the fat test 0.17 per cent and the amount of milk 93.4 lbs., the live weight remaining about the same.
To test the relative feeding value of cotton-seed meal and linseed meal for milk production 5 cows in the early stages of lactation were fed 3 periods of 28 days each. During the first and third periods the rations consisted of 10 parts wheat bran, 10 parts cotton-seed meal, 5 parts corn meal, and 5 parts linseed meal. During the second period the grain ration was the same except that 10 parts of linseed meal were given and 5 parts only of cotton-seed meal. Each cow was fed 45 lbs. daily of corn silage. The results show that cotton-seed meal gave only slightly more returns than linseed meal. Notwithstanding the greater cost of linseed meal the author advises the use of small quantities on account of its tonic effect.

A ration containing one-third cotton-seed meal, supplemented with corn silage, produced no ill effects when fed to cows during the month preceding parturition and to heifers ranging from 6 to 18 months of age. Old pasteurized skim milk did not affect calves, except that when badly curdled it seemed to produce scouris. Feeding skim milk soured with pure cultures of lactic-acid bacteria proved efficacious in checking calf scouris.

Protein and total feed requirements for milch cows (abmelkkühe), J. Hansen (Arch. Deut. Landw. Gesell., 1910, No. 171, pp. 157).—A series of cooperative feeding experiments, along lines of work previously noted (E. S. R., 19, p. 976), with cows which are "milked off." i.e., mature cows which are to be fattened at the end of the lactation period.

It was found that for satisfactory milk production, accompanied by a gain in weight of the cows, an average ration for cows weighing about 1,000 kg. live weight should have a total starch value of from 14.3 to 14.4 kg., of which from 2.5 to 2.7 kg. should be protein. An increase of protein usually raised the milk yield and decreased the gain in weight. These proportions, however, must be varied to suit individual cows.

The "killing-out" system of dairying, J. J. W. Billingsley (Wallaces' Farmer, 35 (1910), No. 8, p. 350).—This is a discussion of the evil effects on the future of dairying by the "killing-out" system, practiced in many localities. This is similar to the "milkling-off" system noted in the article above, dairymen purchasing cows of traders when fresh and when the milk fails to pay for their feed selling them for beef. By this system the cow dealer and dairymen get money, but as the calves are sold to the butcher, and every cow, no matter how valuable she might be as a breeder, is consigned to the shambles at a comparatively young age, the system is destined to retard progress in the future as compared with the breeding-up system, where the best cows are retained as breeders for several years.

Dairy herd records, J. H. Shepperd and W. B. Richards (North Dakota Sta. Bul. 91, pp. 129-168, pls. 6).—This bulletin reports the records of the college herd from 1904 to 1910. The milk records of 24 cows consisting of pure bred and grade Holsteins and Jerseys, pure bred Red Polls, and 1 pure bred Shorthorn are given for the whole period, but the record of milk fat produced and feed consumed has been kept only since 1907. The average amount of milk produced per cow per year for the whole period was 5,265.9 lbs. During the years 1908 and 1909 the averages for the herd were, milk 5,043.9 lbs., fat 206.8 lbs. at a cost of 161 cts. per pound, cost of feed $33.86, net profit $44.76. The largest net profit was $67.90 and the smallest $20.47. Tables are presented showing the records of the cows for their complete lactation periods. A description of each cow and photographs of most of them are included.

The composition of the milk of some breeds of Indian cows and buffaloes and its variations.—I, The milk of some breeds of Indian cows, A. A. Meggitt and H. H. Mann (Mem. Dept. Agr. India, Chem. Ser., 2 (1911), No. 1,
pp. 61, pls. 2).—This contains data on the composition of the milk of cows belonging to the Sind and Gir breeds. The average figures for the fat content of the Gir breed were morning milk 5.2 per cent and evening milk 6.2 per cent, and for the Sind breed the corresponding figures were 6 and 6.3 per cent respectively. The factors affecting the yield and composition of the milk are discussed.

Progress of the dairy industry in Wisconsin, H. C. Taylor and C. E. Lee (Wisconsin Sta. Bul. 270, pp. 3-30, pl. 1, maps 18).—This bulletin reviews the progress made during the decade from 1900 to 1910 in the dairy industry, which it is stated has become the most important branch in agriculture in Wisconsin. The distribution of cows, the relative progress of the creamery, cheese, and condensing industries, the influence of quality of cream on the butter industry, and the division of territory between creameries and cheese factories are discussed and graphically represented by means of maps. Appendices give statistics by counties of cheese factories, creameries, and skimming stations, and of creamery butter and factory cheese production.

Notices of Judgment (U. S. Dept. Agr., Notices of Judgment 995, 1002, 1018, 1028, 1033, p. 1 each).—These relate to the adulteration of powdered milk and the misbranding of condensed milk, butter, and cheese.

A bibliography is appended.

[Pasteurizing milk for children], R. Hanne (Gesundts. Ingen., 34 (1911), No 27, pp. 489–498, figs. 3).—Successful trials are reported in pasteurizing milk after bottling with a new type of pasteurizer, which is illustrated and described.

Pasteurizing of children's milk, M. Neisser (Gesundts. Ingen., 34 (1911), No. 37, pp. 690–693).—A criticism of the method of pasteurizing noted above.

Care of milk (Mo. Bul. N. Y. State Dept. Health, 27 (1911), No. 6, pp. 141–153).—A compilation of data regarding the protection of milk in the dairy, during transportation, and in the home, particularly with reference to its use in infant feeding.

The importance of a certified or pasteurized butter, A. F. Hess (Jour. Amer. Med. Assoc., 57 (1911), No. 7, pp. 561, 562).—Inasmuch as cream contains a larger percentage of tubercle bacilli than the milk from which it is obtained, and the viability of bacilli even in salted butter has been demonstrated, it is urged that butter should be made of pasteurized cream. Although certified butter is considered the ideal product it is deemed out of the reach of the masses because of the extra cost.
Yeasty flavored butter, L. F. Rosengren, (Meddel. Centralanst. Försöksjordbruksområdet, 1911, No. 36, pp. 12; Nord. Mejeri Tidn., 26 (1911), No. 23, pp. 269, 270; N. Y. Produce Rev. and Amer. Cream., 32 (1911), No. 19, pp. 702-704).—The author found that by overripening a starter contaminated with Bacillus lactis acidi (Leichmann) this species appears sooner or later accompanied by yeast fungi in greater or lesser quantities. The bacteria were thus considered not the direct cause of yeasty taste in butter, but indirectly in proportion as they favored the development of the yeast in the starter, the cream, and the butter. This apparently explains why a yeasty taste occurs in butter, where the ripening temperature usually is below 20° C., as although this is a temperature lower than that at which the long lactic-acid bacteria grow it is favorable to the yeast. Directions for handling the milk in order to prevent the defect are given.

Butter scoring contest for 1910, L. M. Davis (California Sta. Circ. 60, pp. 2-27, figs. 2).—This is the report of the second annual educational butter-scoring contest (E. S. R., 23, p. 285). The method of scoring the butter is noted and methods of making the highest and lowest scoring butters are described. Suggestions are offered for improving the quality of cream delivered at creameries, and notes are given on the efficiency of the cream cooler and the effect of insulating cream cans. A formula is given for calculating the overrun, together with directions for making the Babcock test for milk fat in butter.

"One of the most conspicuous features noticed in connection with the second contest, as well as the first, is the poor quality of cream which is generally received at California creameries."

Experiments in making cheese with pure cultures, O. Gratz, (Kisérlet. Közlém., 14 (1911), No. 3, pp. 418-432, fig. 1).—In the manufacture of Óvár cheese the addition of from 0.5 to 2 per cent of the pure culture lactic-acid bacteria of the Streptococci group hastened ripening and improved the texture and flavor. Less than 0.5 per cent was without any appreciable effect. With cultures of Bacillus casei the characteristic flavor of the cheese was lost.

VETERINARY MEDICINE.

Handbook of comparative microscopic anatomy of domesticated animals, W. Ellenberger (Handbuch der vergleichenden mikroskopischen Anatomic der Haustiere, Berlin, 1911, vol. 3, pp. XXI+556, figs. 493).—In this third and final volume (E. S. R., 24, p. 777) the digestive system is dealt with by W. Ellenberger, the respiratory system by M. von Sussdorf, and the diaphragm and serosa by A. Trautmann.

In regard to the influence of bacterial toxins upon animal tissue, W. Viehmann (Arch. Path. Anat. u. Physiol. [Virchow], 261 (1919), No. 3, pp. 419-427, pl. 1; abs. in Ztschr. Immunolog., u. Expt. Ther., II, Ref., 3 (1919), No. 9, p. 898).—A description is given of the various histological changes which occur in the more important organs in acute and chronic poisoning by bacterial toxins. The action upon the kidney, suprarenals, spleen, lungs, and heart, and the local reaction are considered.

The distribution of hemolysins, agglutinins, and poisons in fungi, especially the Amanitas, the Entolomas, the Lactarius, and the Inocybes, W. W. Foron (Jour. Pharmacol. and Exptl. Ther., 2 (1911), No. 4, pp. 315-318).—The fungi which are known to be poisonous to man, such as A. muscaria, A. phalloides, A. verna, A. virosa, L. torminosus, L. velutus, and Clitocybe illudens, are acutely poisonous to animals on subcutaneous inoculation, in but 2 instances, L. velutus and C. illudens, this poisonous action being limited to guinea pigs.

"A number of other species, such as A. chlorina, A. porphyria, A. morrissii, A. specta, L. infelix, and others, the properties of which have not apparently
been tested, resemble the poisonous forms so closely in their action upon animals as to leave little doubt that their ingestion by man is likely to be followed by serious consequences.

"Certain genera, such as the Entolomas and the Hypholomas, exhibit a uniform toxicity for guinea pigs only (except E. strictius, which is poisonous also to rabbits). These genera include both edible and poisonous species, but no fatalities have thus far been reported from their consumption. Further experience must determine in how many of these species the poisonous substances found are harmful when taken into the intestinal tract of man.

"The fungi described in this paper which are known to be edible are either free from action upon both rabbits and guinea pigs or produce at times a chronic intoxication in guinea pigs only. A number of fungi whose properties are not described in the literature are without action upon animals. Those species are in all probability harmless to man.

"Poisonous fungi may be divided into 3 groups, (a) those containing poisons acting on the nerve centers, example, A. muscaria; (b) those producing degenerative changes in the internal organs, examples, A. phalloides, A. verna, etc.; (c) those causing gastro-intestinal disturbances of a more or less violent character, examples, L. torminosus, C. illudens, E. sinuatum, etc."

See also a previous note (E. S. R., 24, p. 384).

Leucoprotease and antieleucoprotease, C. H. B. Bradley (Jour. Hyg. [Cambridge], 10 (1910), No. 2, pp. 209-230, figs. 2; abs. in Jour. Chem. Soc. [London], 98 (1910), No. 577, p. 795, 796).—"Lymphoprotease is a pepsin-like enzyme associated with mononuclear leucocytes. Leucoprotease is a trypsin-like enzyme associated with polynuclear leucocytes, and was in the present experiments obtained from pus cells. Experiments on its rate of action are given. It acts only in neutral or faintly alkaline media. The antitryptic action of serum varies in different animals, and in the same animal under different conditions (disease, etc.). In the present experiments, the variation in mammals was slight, and immunization with leucoprotease caused only a small increase of antitryptic activity. Goats were the animals used."

[Diseases of domestic animals in Mexico] (Estac. Agr. Cent. [Mexico], 1909, Bols. 15, pp. 13, pls. 2, figs. 2; 21, pp. 12, pls. 3; 1910, Bols. 49, pp. 43, pl. 1, figs. 13; 42, pp. 27).—In these bulletins E. L. Vallejo discusses bovine pirosis, the affection of sheep due to Oestrus ovis, and liver rot in ruminants, and E. Fernandez an affection of equines, that occurs in the States of Tabasco, Chiapas, Vera Cruz, etc., and is caused by the bite of Enypelma longipes.

Report of the territorial veterinarian, V. A. Norgaard ([Bien.] Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1909-10, pp. 175-231, pls. 13).—In this report on the details of the work accounts of the occurrence of stock disease are included. Reports of the assistant and deputy veterinarians are appended, the former giving accounts of investigations of redwater in cattle, eye worm in chickens, and sheep botflies in California rams on the island of Lanai.

Annual reports of proceedings under the diseases of animals acts, the markets and fairs (weighing of cattle) acts, etc., for the year 1910 (Bd. Agr. and Fisheries [London], [Vet. Dept.], Ann. Rpts. Proc. 1910, pp. 108, pls. 2).—The reports of the chief veterinary officer, S. Stockman (pp. 4-32), and of the assistant secretary animals division, A. W. Anstruther (pp. 33-50) include accounts of the occurrence of foot-and-mouth disease, hog cholera (swine fever), glands, anthrax, sheep scab, a trypanosome of British cattle, bracken-poisoning, warbles, etc., and of the habits of Haemaphysalis punctata. Plates showing the occurrence of hog cholera and sheep scab from 1908 to 1910 are included.

Various statistical data on the occurrence of diseases, international trade in animals, etc., are presented in an appendix.
In regard to the diagnosis of anthrax with the precipitation method, K. Bierbaum (Berlin, Tierärztl. Wehnschr., 27 (1911), No. 12, pp. 292-293).—
The results show that it is possible, as previously shown by Ascoli, to detect anthrax after putrefaction has taken place and where the bacteriological examination has failed to reveal it.

**Endemic Malta (Mediterranean) fever in Texas with the isolation of the Micrococcus melitensis from two patients, E. R. Gentry and T. L. Ferenbaugh (Jour. Amer. Med. Assoc., 57 (1911), No. 11, pp. 889-891, figs. 2).**—This is a report of a laboratory and clinical study of 2 cases of Malta fever in man, which had been previously noted (E. S. R., 25, p. 685), and which had entered on a relapse.

The organism isolated from the blood was found to agglutinate a specific serum in high dilution, to render milk alkaline, and not to ferment glucose. In practically all respects the organism resembled *M. melitensis*. The temperature charts, blood cell counts, and symptoms are given in detail.

The conclusion reached is that "endemic Malta fever exists in Texas at the present time."

**Endemic Malta (Mediterranean) fever in Texas, E. R. Gentry and T. L. Ferenbaugh (Jour. Amer. Med. Assoc., 57 (1911), No. 13, pp. 1045-1048, figs. 3).**—Continuing previous work the authors report the clinical and laboratory findings with 5 new cases of Malta fever. In 2 of these cases goat's milk was not drunk at all, but the patients, who were children, played in dusty goat pens.

In addition, a bacteriological examination was made of some animals from a herd of 32 Maltese female goats) from which the milk taken by some of the patients was obtained. The serum from 8 of these goats (34.7 per cent) agglutinated the *Micrococcus melitensis*. *M. melitensis* was not isolated from the goats.

**[Endemic Malta (Mediterranean) fever in Texas], E. R. Gentry and T. L. Ferenbaugh (Jour. Amer. Med. Assoc., 57 (1911), No. 14, p. 1127).**—According to this report, 25 out of 128 goats taken from 3 herds which contained in all about 3,000 animals, gave a positive agglutination test for *Micrococcus melitensis*. "Only 8 of these had milk and they only in small quantity. Specimens of milk plated out on glucose-nutrose-litmus-agar gave a negative result for *M. melitensis* in each instance."

The results obtained by the intravenous injection of trypanblue in the plasmosis of domesticated animals with especial reference to gall sickness, G. T. Henderson (Vet. Rec., 27 (1911), No. 1199, p. 4).—The author reports 3 cases of gall sickness due to *Anaplasma marginale* and *Piroplasma mutans*, in which trypanblue was used with beneficial results. He states that he has found trypanblue to give highly successful results in all the piroplasmoses of domesticated animals other than that due to *P. parvum*.

**The transmission of Spirochaeta duttoni, E. Hindle (Parasitology, 4 (1911), No. 2, pp. 133-149).**—"About 30 per cent of the *Ornithodoros moubata* from Uganda have been found to be immune to infection with *Spirochaeta duttoni*...

"The spirochetial infection that may follow the bite of an infected *O. moubata* results from the entrance of the infective material, excreted by the tick whilst feeding, into the open wound caused by the tick's bite. It is not the result of the inoculation of infective material from the salivary glands."

**Sleeping sickness and animal trypanosomiasis in Senegal, A. Theoux and L. D'Anfreville de la Salle (La Maladie du Sommeil et les Trypanosoma-**

---

Strongyloides infections in man and animals in the Isthmian Canal Zone, S. T. Darling (Jour. Expt. Med., 12 (1911), No. 1, pp. 1-24, pls. 3).—"From a study of strongyloides infections in man and animals in this region, it has been determined, in confirmation of the views of Grassi, Calmette, and others, that they are not causative factors in the production of diarrhea. The mother worm, however, burrows into the mucosa and deposits her ova there. Certain tissue reactions take place and are evidenced by the cellular proliferation in those portions of the intestines occupied by the nematodes."

"In animals, there is an associated anemia, not positively attributable to the strongyloides, but, on the other hand, not attributable to any other cause. It is possible that Strongyloides stercoralis may cause some degree of anemia in man. The amount is indeterminable in this region among hospital cases on account of the associated hook-worm disease or malaria.

"Portals of entry for various microorganisms are made by the mother worm and her larvae in the small intestine, and, while no case of general bacterial infection has been proved to have arisen in this way, its occurrence is possible and highly probable. . . ."

"From a correlation of culture study with the results of a histological examination of the invaded mucosa, this explanation of the derivation of the two phases is suggested. The mother worm in the intestinal tract has two kinds of progeny: (a) those expelled into the crypts or lumen, and (b) those imbedded in the intestinal wall. One lot becomes larve of either the direct or indirect phase; the other lot of the opposite phase. It appears to me that the intraepithelial cell-developed larva furnish the direct phase, while the embryos expelled directly from the mother become the indirect phase larva. . . ."

"Cold merely inhibits the development of the larvae into either the filariform (direct) or into the sexually differentiated adults, and does not alter the anlage."

"The resistant as well as the infecting form is the filariform larva, and all chemical larvicides must be directed against this form. Thymol and an alkaline cresol resin soap were found to be effective larvicides for the filariform larva."

Two new strongyloides of the monkey and ant bear are described. Cultures of these nematodes show a predominance of the indirect mode of development.

Experimental infection of mammals, birds, and cold-blooded vertebrates by homogenous cultures of Koch's tubercle bacillus, F. Arloing (Compt. Rend., Soc. Biol. [Paris], 68 (1910), No. 14, pp. 701-703; abs. in Centbl. Bakt. [etc.], 1. Abt., Ref., 37 (1910), No. 22-24, p. 714).—The author tested the pathogenic action of the human type of tubercle bacillus cultivated deep in bouillon upon various kinds of animals, and found that in cultivating by such means the bacillus loses much of its virulence.

The following order of susceptibility was established for mammals, viz., bovine, sheep, goat, rabbit, and dog; for birds, the fowl and pigeon; and for cold-blooded vertebrates, the frog and fish. In the ruminants the severest pathological condition was found to occur in the lungs; while in the rabbit it was present in the liver and spleen. In the frog and fish the changes mani-
fested themselves in the serous membranes. In the dog no macroscopical changes were visible.

The detection of tubercle bacilli by the antiformin-ligroin method, with particular reference to intestinal tuberculosis, H. Hall (Über den Nachweis der Tuberkelbazillen durch das Antiformin-Ligroinverfahren unter besonderer Berücksichtigung der Darmtuberkulose. Immu. Diss., Univ. Giessen, 1909, pp. 29; rev. in Ztschr. Fleisch u. Milchhyg., 21 (1911), No. 7, pp. 218, 219).—Hasse-rodts's procedure was utilized in these tests, and with it the author determined that all bacilli which were contained in the feces of sheep, bovines, and dogs, with the exception of the tubercle bacillus, were dissolved. It is pointed out, however, that tubercle bacilli which had been exposed for 24 hours to a 15 per cent antiformin solution were not capable of producing tuberculosis in guinea pigs.

In regard to the diagnostic and prognostic value of Russo's methylene blue reaction for tuberculosis, J. von Szalóky (Ztschr. Tuberkulose, 17 (1911), No. 3, pp. 261–267).—According to Russo this reaction is as accurate as Ehrlich's diazo reaction and is less complicated. The test consists of adding from 4 to 5 drops of a 1 per cent methylene blue solution to from 4 to 5 cc. of urine. After shaking the mixture, if the reaction is positive the urine assumes an emerald-green color, but if negative it remains blue. The test was tried with 33 nontuberculous subjects and with 195 tuberculous patients, of whom 30 were in the first stages of the disease, 65 in the second, and 100 in the third.

From the tests the author concludes that the reaction is of very little value as a diagnostic agent, but that where the reaction is constantly present in pulmonary tuberculosis it indicates a bad prognosis. He considers it nearly as valuable as Ehrlich's diazo reaction, and believes that it would be advisable to introduce it in general practice on account of its simplicity. He does not consider the reaction a purely colorimetric one.

Tests in regard to the action of various tuberculins when given internally, T. Pfeiffer and J. Leyacker (Wiener Klin. Wochenschr., 23 (1910), No. 50, pp. 1797–1799, fig. 1; abs. in Ztschr. Immunisat. u. Expt. Ther., II, Ref., 3 (1910), No. 13, p. 1101).—Neither old nor new tuberculin nor other tuberculins (intubertoxy1 capsules containing 0.002 cc. of old and 0.002 cc. of new tuberculin (Koch), 0.2 gm. of cresote carbonate, and 0.02 gm. of atoxyl phthisoremid capsules containing new tuberculin and tuberol) when given per os yielded any reactions typical of tuberculin.

Convenient table in the use of tuberculins, G. H. Kress (Jour. Amer. Med. Assoc., 56 (1911), No. 17, pp. 1252, 1253).—This is a table for calculating the dilution of tuberculins for proper dosage.

Actinomycosis in cows' udders, J. Riddoch (Jour. Meat and Milk Hyg., 1 (1911), No. 6, pp. 323, 324, fig. 1).—A brief account of a case of this affection.

On the action of Senecio alkaloids and the causation of the hepatic cirrhosis of cattle (Pictou, Molteno, or Winton disease), A. R. Cushny (Jour. Pharmacol. and Expt. Ther., 2 (1911), No. 6, pp. 531–538).—The author's experiments indicate that the alkaloids of Senecio latifolius are capable of producing the symptoms and lesions characteristic of this disease. His results seem to indicate that S. jacobea is devoid of the properties of S. latifolius whether the plant is grown in England or in Canada. "This is however incompatible with the results of Gilruth and Pethick, who showed definitely that the disease in Canada and New Zealand is due to this species. The dis-
crepancy between these results and mine may probably arise either from the plant from which my preparations were made having been collected at the wrong season, or possibly from the poisonous principle having undergone change into some inert form in the course of preparation or drying.

"S. sylvaticus collected in Yorkshire in August proved equally inactive. S. vulgaris or common groundsel collected in England and prepared in the same way proved poisonous, a cat which received the extract from 2 gm. of the dried plant dying in 10 days with symptoms resembling those arising from senecifoline, but with more marked diarrhoea. The post-mortem findings were similar to those observed from senecifoline."

In regard to the enzym and streptococci content of milk obtained under aseptic conditions, W. Rullmann (Arch. Hyg., 73 (1910), No. 1, pp. 81-144).—Out of 84 milks which were obtained under aseptic conditions 20 were found to be free from bacteria, and with a great many samples the number of organisms was from 2 to 5 germs per cubic centimeter.

The enzym content was determined in the 20 germ-free samples, and from this it could be noted that catalase, direct oxidase, peroxidase, Schardinger’s enzym, and diastase are original constituents of milk, while reductase, hydrogenase, and salolase are of bacterial origin. In these tests it was often possible to detect strains of micrococci which were capable of producing reductase and catalase in sterile milk and at a temperature of 37° C. It was also noted that milks obtained from cows affected with mastitis contained a large amount of catalase, Schardinger’s enzym, and reductase, and that Schardinger’s reagent could be decolorized by artificially sterilized germ-free milk, though a much longer period of time was required than with ordinary milk. The author was also able to note that the teats on each side of the udder were intimately connected. When large amounts of leucocytes were present in the milk the acidity content of the milk was low, and a decrease of the bacterial content of milk took place when the milk was allowed to stand for a long period.

In regard to the mastitis problem, the author concludes that the Trommsdorff leucocyte test is of great value as a diagnostic agent, and where an unusually large sediment has been obtained in the centrifuge tube he recommends a microscopic examination for streptococci and also the inoculation of the sediment into bouillon. Ernst’s tester for detecting mastitis, according to the author, is an efficient apparatus for the control of the disease in the barn and is easily handled.

In regard to the biology of the hog erysipelas bacillus and two organisms which are morphologically similar, Schipp (Deut. Tierarztl. Wehnschr., 18 (1910), No. 8, pp. 113-117; abs. in Ztschr. Fleisch u. Milchhyg., 21 (1910), No. 1, pp. 20, 21).—Two bacilli were isolated from a bovine (A) and from chickens (B), which closely resembled Bacillus erysipelas suis. These were subjected to a biological examination (agglutination and opposite immunization), the results of which showed that the (B) bacillus was identical with the erysipelas bacillus. This bacillus, according to the author, had an increased virulence, and in this way was capable of producing a lethal infection in the fowl but when cultivated in the laboratory it lost much of its aggressiveness. On the other hand, like other erysipelas strains, it retained its toxicity for mice for a long period of time.

Murrina, a trypanosomal disease of equines in Panama, S. T. Darling (Jour. Infec. Diseases, 8 (1911), No. 4, pp. 467-485, fig. 1).—This is a report of studies of the fatal type of equine trypanosomiasis known in Panama as “murrina” and “derrengadern,” a preliminary account of which has been previously noted (E. S. R., 23, p. 486). It is stated that at least 23 animals were destroyed by this disease during the year prior to April, 1910.
"The chief distinguishing features of the disease are anemia, weakness, emaciation and edema, conjunctival ecchymoses, conjunctivitis, pyrexia, and some posterior paresis. The pathological findings are constant and characteristic: Splenic capsular ecchymoses; acute hemorrhagic nephritis, with acute glomerulitis and petchii; hemorrhages in renal lymph nodes; epicardial and endocardial ecchymoses; and less constantly pleural, peritoneal, and conjunctival ecchymoses, and pleural effusion. The blood changes are those of anemia with lymphocytosis. There is much phagocytosis of blood pigment by endothelial cells of the liver and spleen.

"The disease is probably transmitted mechanically by flies through the broken skin of cuts and various wounds. Saddle horses were not infected, and there are no evidences that any animals were infected by means of Stomoxys or tabanids or by ticks or bats.

"The epidemic, which threatened to destroy several hundred mules and horses, has been controlled (there having been no new case in 6 months) by detection of infected animals, by means of daily routine temperature records throughout the corral, the microscopic examination of the blood of all animals having a temperature above 100° F., the isolation in screened stables of infected animals or suspects, and the sacrifice of all infected animals."

The probable mode of infection and the methods used in controlling an outbreak of equine trypanosomiasis (murrina) in the Panama Canal Zone, S. T. Darling (Parasitology, 4 (1911). No. 2, pp. 83-86).—The information here presented is included in the account above noted.

Investigations of Beschälseuche, Zwick and Fischer (Arb. K. Gesundtsamt., 36 (1910), No. 1, pp. 1-103, figs. 22, charts 24; abs. in Sleeping Sickness Bur. [London] Bul., 3 (1911), No. 23, pp. 28-31).—The authors point out that this disease of horses has been prevalent at times in Germany and other parts of Europe for the last 100 years. The following conclusions arrived at are based on examinations of 26 infected horses:

"Beschälseuche is caused by trypanosomes which in their essential characteristics correspond with Trypanosoma equiperdum. These trypanosomes are, like those of dourine, transmissible to small experimental animals, as well as to cats, dogs, and horses. They produce in these animals a disease picture which completely corresponds with that of artificially produced dourine. Sheep also have shown themselves susceptible to infection; on the other hand, several attempts made to infect a goat and a cow failed. Beschälseuche and dourine are essentially identical diseases. The trypanosomes in pregnant animals sick of Beschälseuche can pass from the mother to the young. Beschälseuche does not spread except by coitus; the transmission of the disease in natural conditions does not occur by intermediaries (biting flies). For demonstrations of the trypanosomes in horses suspected of the disease one may use, (1) the microscopical examination of the mucous membrane of the vagina and urethra, as well as of the fluid contents of the local skin swellings as soon as possible after their appearance, and moreover cultures in blood bouillon: (2) inoculation under the skin or the peritoneum of white mice, guinea pigs, rabbits, and dogs of the fluid contents of these specific skin swellings and, according to the size of the experimental animals, of larger or smaller quantities of defibrinated and centrifuged blood diluted with physiological salt solution. Agglutination and the fixation of complement are not, as far as observations go, suitable methods for diagnosis of Beschälseuche. The serum of a horse suffering from Beschälseuche and of 2 sheep artificially infected with Beschälseuche trypanosomes exercised a protective action in white mice, which was not, however, quite reliable against an otherwise lethal infection with the trypanosomes of Beschälseuche and dourine. This serum does not protect, however, against such an infection with nagana trypanosomes.
"We often succeeded by means of a single injection of arsphenylnitroglycerin (1 cc. of a solution of 1:150 to 1:300) in permanently curing infected white mice; also in the case of rabbits and dogs favorable results were attained with the preparation. Our experiments and observations, as far as they have gone, are not yet sufficiently advanced for us to give an estimate of the action of the medicament in horses."

A bibliography of 79 titles is appended to the account.

In regard to the treatment of equine influenza, Minder (Schweiz. Arch. Tierheilk., 52 (1910), No. 5, pp. 340-350; abs. in Ztschr. Immunitätsf. u. Expt. Ther., II, Ref., 3 (1910), No. 8, p. 84).—The author reports his results with a curative serum for equine pneumonia. This serum is produced with a view of having its action directed to both the pneumostreptococcus and the ovid bacterium (Pasteurella equi).

The results with 16 out of 17 horses were considered good.

Etiology of canine distemper, N. S. Ferry (Jour. Infect. Diseases, 8 (1911), No. 4, pp. 399-420).—"Canine distemper is found, as a result of this research, to be an acute infectious disease primarily of the respiratory tract of the young dog, caused by a micro-organism first described by me [E. S. R., 24, p. 285], to which I have given the name Bacillus bronchicanis.

"These assertions are based on the following facts:

"When cultures are taken early in the disease B. bronchicanis is found in the respiratory tract in every case, and, if taken in the first stage, is found uncontaminated. B. bronchicanis was isolated from 97 dogs at autopsy. In 68 cases it was isolated in pure culture either from the respiratory tract or blood. Of 29 positive blood cultures it was found 18 times, in 13 of which it was unaccompanied by any other organism. B. bronchicanis was isolated from the only case attempted during life, in the very earliest stage, by means of the bronchoscope. The serum from cases of distemper in all stages has given positive agglutination with B. bronchicanis, while the controls were invariably negative. Koch's law has been fulfilled and cases of typical distemper have been produced by artificial inoculation with pure cultures, the bacillus being again isolated and grown in pure culture, all under conditions which have precluded infection from any other source."

A list of 44 references is appended.

In regard to the results of vaccinating with Piorkowski's serum against canine distemper, Böden (Berlin. Tierärztl. Wochenschr., 26 (1910), No. 47, pp. 929-933).—The author details his experience with Piorkowski's serum against canine distemper in 22 cases. As a result of his findings he believes the serum can only be employed to advantage in acute cases, or where a slight catarrh of the respiratory channels and the conjunctiva exists, and where a high initial fever exists or has existed.

Prophylaxis against echinococcus disease, P. Barbaschi (Gaz. Osped. e Clin. [Milan], 31 (1910), No. 116, pp. 1225-1227; abs. in Zentrbl. Gesam. Physiol. u. Path. Stoffwechsel, u. ser., 6 (1911), No. 5, p. 202).—The author injected increasing amounts of sterile echinococcus cystic fluid (from 3 to 60 cc.) into dogs, and later on gave them 400 living echinococcus heads. The dogs did not become sick, and after a period of 2½ months no parasite could be detected in the intestinal tract. As immunity against the disease can be confered upon the young through the placenta, the author recommends the obligatory immunization of female dogs against the disease.

A new species of cestode parasite (Tænia balaniceps) of the dog and of the lynx, with a note on Proteocephalus punicus, M. C. Hall (Proc. U. S. Nat. Mus., 39 (1911), pp. 139-151, figs. 9).—The species here described as new was taken from a dog from Fallen, Nev., and from a lynx (Lynx rufus maculatus) from southern New Mexico.
EXPERIMENT STATION RECORD.

Scabies of the rabbit, W. Jowett (Jour. Comp. Path. and Ther., 24 (1911), No. 2, pp. 134-136, figs. 2).—The author records cases in which the trunks of rabbits were affected.

Tuberculosis in fowls (Michigan Sta. Circ. 12, pp. 83-86 figs. 2).—Attention is called to the importance of an early recognition of this disease, which has been found in flocks in several counties of Michigan and occasionally in market chickens. Mention is made of a large flock of mixed Black Minorcas and Brown Leghorns that was found in Livingston County, badly affected with tuberculosis. Attention is also directed to the fact that the tubercle bacillus has been found in the white of eggs of affected fowls and to the danger of infection in drawing the intestines and other viscera of diseased birds.

“When a positive diagnosis has been made, the best solution of the problem seems to be to kill the whole flock and use those not affected for food, burning the diseased ones. After this, a careful disinfection of the chicken house and yards is necessary before it is safe to introduce new birds. As a preventive may be recommended the exclusion of the disease by raising stock from eggs known to have come from healthy birds, and refusal to buy stock from poultrymen that can not offer evidence of flocks free from tuberculosis.”

The infective granule in certain protozoal infections, as illustrated by the spirochetosis of Sudanese fowls, A. Balfour (Brit. Med. Journ., 1911, No. 2622, p. 752).—The author, working in Khartum, has found through use of the dark-field method, especially by practicing liver puncture on chicks at the crisis or on chicks which have been given a sufficiently large dose of “Salvarsan,” that in the liver in particular, also in the spleen and lungs the causative agent of fowl spirochetosis undergoes a remarkable change. The spirochetes discharge spherical granules from their periplastic sheath which apparently enter the red cells, develop in them, and complete a cycle of schizogony. It is stated that Fry, who confirms the author’s observations, “has previously seen a shedding-off of granules by trypanosomes in the peripheral blood of experimental animals.” The author thinks that it is these spirochete granules in the liver, spleen, and lungs, and possibly also in other internal organs, that invade the red cells. “Such a chain of events fully explains all the puzzling features which this intracorpuscular infection has hitherto presented, and, moreover, brings it into line with the infective granules found in the ticks, for these very closely resemble those seen in liver juice films, both when examined by the dark-field method and when stained by the Levaditi process.”

That these granules have not previously been observed is thought to be explained by the fact that they apparently do not take on the Romanowsky stain. The author’s observations lead him to conclude that this fowl spirochete must be classed as a species, for which he proposes the name Spirocheta granulosa penetrans. Since these granules have been found to be resistant forms, it is thought that their presence in countless numbers in the tissues may explain part of the mechanism of relapse and the difficulty in curing completely some of the chronic, spirochetal infections, such as, for example, syphilis and yaws.

Feeding experiments in fowl spirochetosis, A. Balfour (Lancet [London], 1911, II, No. 4, pp. 223, 224).—In feeding experiments here reported, the author has found that “if healthy chicks be fed on ticks (Argas persicus), which themselves have recently fed on birds infected with Spirocheta granulosa penetrans, the fowl spirochete of the Sondan, the chicks speedily develop spirochetosis. Not only so, but if healthy chicks be fed on a sufficient number of ticks which, having fed a long time previously on spirochete infected birds, harbor, not spirochetes, but granules only, these chicks likewise become infected through the alimentary canal. In both cases the incubation period is short, in one instance it was very short, and it may be said that care was taken to exclude any other possible source of infection.”
Further observations on the cecal parasites of fowls, with some reference to the rectal fauna of other vertebrates, C. H. Martin and Muriel Robertson (Quart Jour. Micros. Sci. [London], n. ser., 57 (1911), No. 225, pp. 53–81, pls. 5, figs. 4).—The flagellates Chilomastix gallinarum, Trichomonas gallinarum, T. cecithi, and Trichomonastix gallinarum are the species to which particular attention is given in this paper.

RURAL ECONOMICS.

Urban and rural population of the United States (U. S. Dept. Com. and Labor, Bur. Census [Press Bul.], 1911, Aug. 21, folio).—This is a preliminary statement issued by the Bureau of the Census showing comparative figures as to urban and rural population in the United States for the last 20 years. Urban population is defined as that residing in cities and other incorporated places of 2,500 inhabitants or more.

The proportion of total population living in urban and rural territory at the censuses of 1910, 1900, and 1890 is shown below:

Of the total increase in population during the past decade about seven-tenths was in urban territory and three-tenths in rural territory. It is shown that in every State and Territory there has been since 1900 an increase in urban population, while in 7 States there has been an actual decrease in rural population. Urban population has increased faster than rural population in every State except Montana and Wyoming.

It is further pointed out that in no State or Territory was the increase in urban population less than 10 per cent. In 13 States it was between 50 and 100 per cent, and in 6 States more than 100 per cent. There were 22 States in which the rural population either decreased or showed an increase of less than 10 per cent, and only 8 States where there was an increase of more than 50 per cent.

Other tables are given showing the urban and rural population in the United States by States and Territories in 1890, 1900, and 1910.

South's marvellous agricultural progress (Monhrs. Rec., 60 (1911), No. 5, pp. 45, 46).—This article presents by notes, statistics, and Illustrations the agricultural progress of the South from 1900 to 1910. Compared with the country as a whole the increases in certain farm lines are shown as follows:

Comparative value of farm lands, buildings, machinery, etc., in the South and in the United States.
Additional tables are given showing the aggregate value of farm lands by States, also the value of farm buildings and farm machinery, improved acreage, expenditures for labor and fertilizers, the average value per acre of lands alone and the values of 12 leading crops in 1900 and 1910.

_Yearbook, 1910 (N. Dak. Mag., 4 (1911), No. 4, pp. 272, pl. 1, figs. 206)._—This publication gives a historical and descriptive sketch of the State of North Dakota by counties, showing the agricultural, social, and political history of each, supplemented by statistics concerning their population, and the commercial, industrial, and agricultural growth during the past year.

[Agriculture in Canada], J. W. Robertson et al. (In Lands, Fisheries and Game, and Minerals. Ottawa: Com. Consr., 1911, pp. 1-33)._—This report presents results of an agricultural survey of representative areas in each province, made by special agents of the Canadian government under the supervision of the officers of the provincial departments of agriculture and the agricultural colleges. Visits were made to 100 or more representative farms in each province and the information obtained is considered fairly representative of the actual conditions in each regarding the “preservation of soil fertility, the inroads of weeds and insect pests, and the practice of well-planned farming as shown by systematic rotation of crops, the practice of sowing selected seeds, and the application of manures or other fertilizers.”

Tables are given showing the area of field crops, and the yield and value of farm products in the various provinces.

_Conservation of the soil, W. H. Taft (U. S. Dept. Agr., Office Secretary Circ. 35, pp. 8)._—This is an address before the National Conservation Congress, at Kansas City, Mo., September 25, 1911, in which the present status of agriculture in this country is discussed, together with the outlook for future development along the lines of soil conservation, business administration, and agricultural education. It is believed that the adoption of improved methods will so stimulate production that “we may look forward to the middle of this century, when 200,000,000 of people shall swear fealty to the starry flag, as a time when America will still continue to feed her millions and feed them well out of her own soil.”

_The country-life movement, L. H. Bailey (New York, 1911, pp. 11+220)._—The author makes a careful distinction between the “country-life movement” and the “back-to-the-farm” agitation, showing that the former “is the working out of the desire to make rural civilization as effective as other civilization,” and the latter is in part “the result of the doubtful propaganda to decrease the cost of living by sending more persons to the land, on the mostly mistaken assumption that more products will thereby be secured for the world’s markets.”

A greater portion of the book is devoted to a discussion of some of the agencies for a more equal development of social and economic conditions in country and city life.

_The Bavarian Central Loan Bank (Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Intel., 2 (1911), No. 6, pp. 12-14)._—This bank was founded in 1894 as a limited liability company to serve as a kind of clearing house for the Bavarian agricultural credit banks, which deposit with it their surplus funds and receive loans from it, thus preserving to some degree an equilibrium between societies with surplus funds and those in need of money. It deals entirely with the affiliated agricultural banks and by fixing practically a uniform rate of interest it prevents to a large extent its members from suffering by fluctuations in the market rate of discount.
In 1909 the Central Bank founded a special land purchase department to assist cooperative credit banks in buying and selling land. Up to the present time 35 peasant holdings have been bought and sold again by the Central and the local banks.

**Agricultural statistics of Bulgaria** (Zeml. Statis. (Statis. Agr.), 1909, pp. 76).—This report gives tables showing the amount of cultivated land, the yield and estimated value of farm crops, live stock, etc., by departments and subdivisions during the year 1909.

**Agricultural statistics of Bengal for 1909–10** (Agr. Statist. Bengal, 1909–10, p. 77).—Statistics are given showing the acreage, classification of areas, and status of irrigation, crops, current fallows, and stock in cadastrally-surveyed areas in Bengal, and the transfer of land in each district for the year ended with March, 1910.

**Legal weights (in pounds) per bushel of various commodities** (U. S. Dept. Com. and Labor, Bur. Standards Circ. 10, pp. 10).—This circular shows the legal weights per bushel of various commodities as fixed by national or state legislation.

In many cases the weights of similar commodities differ considerably in different States. It is also pointed out that on account of variations in the densities of commodities in different localities and in different seasons, the weight of a given volume has only been approximately fixed for these commodities, so that in transactions involving the measure of such commodities it is important that it be distinctly understood whether the U. S. bushel, viz, the volume of 2,150.42 cu. in., or a certain fixed number of pounds is meant.

The circular recommends that all sales of agricultural commodities be made by weight.

**AGRICULTURAL EDUCATION.**

Addresses and proceedings of the National Education Association, Boston, Mass., 1910 (Addresses and Proc. Nat. Ed. Assoc., 48 (1910), pp. XI–1124).—The papers presented before the department of rural and agricultural education of the National Education Association at its convention in Boston, Mass., July 2–8, 1910, included the following:

*Value of demonstrative methods in the agricultural education of the rural population*, H. L. Russell (pp. 107–111).—The author holds that the economic need of the hour is increased production and that agricultural education should be extended to the man on the farm. The means employed at the University of Wisconsin are described.

*Field laboratory work accompanying college courses in horticulture*, R. L. Watts (pp. 1082–1087).—Some of the field laboratory work connected with the courses in horticulture as given at the Pennsylvania State College is outlined.

*Field laboratory work*, K. C. Davis (pp. 1087–1089).—The exercises which must be taken outside the school room and which have a most direct bearing on agriculture are grouped as those which deal with (1) soils, (2) plants, (3) animal life, and (4) machines, tools, and buildings. The exercises in field laboratory work at a well-established agricultural high school are given as an example of how the work may be accomplished elsewhere than on the school farm.

*Laboratory and field work in the agricultural high school*, B. H. Crocheron (pp. 1090–1093).—This paper discusses four difficulties encountered in at-
tempting field and laboratory work in an agricultural high school. These difficulties are (1) lack of available information as to the best exercises, (2) lack of materials, (3) lack of time in which to prepare exercises for presentation, and (4) the difficulty in preserving the proper sequence so as to articulate with the text-book work. The community work which the Agricultural High School of Baltimore County, Md., is doing (E. S. R., 25, p. 598) is also described.

The place of agriculture in the public high schools, G. F. Warren (pp. 1094-1103).—The author discusses the question of how much education a farmer needs, citing the results obtained in the farm-management investigations in four New York townships previously noted (E. S. R., 25, p. 594), concluding that a high school education is worth more to these farmers than an endowment of $6,000 in 5 per cent bonds. Other subjects discussed are what schools and instructors should teach secondary agriculture, the place of agriculture in the high school course, and the object in so teaching it.

The place of the agricultural high school in the system of public education, D. J. Crosby (pp. 1163-1167).—This paper consists chiefly of a discussion of two things which seem to the author to be essential in a system of universal public education, viz: (1) A standard graded course of instruction leading from the kindergarten through the university to the learned, technical, and business professions, and (2) adequate provision for those who can not pursue the whole course, or who, for any reason whatever, have gotten out of the direct line of the standard course. A brief summary is given as to the influence of agricultural high schools and their place in a system of public secondary education.

How the schools and the United States Department of Agriculture can cooperate, W. M. Hays (pp. 1108-1113).—The major portion of this paper consists of an analysis of the existing secondary educational situation in order to give a viewpoint of the complex relationship of this Department to other educational institutions. There is also a brief review of what the Department is already doing along economic and educational lines.

Opportunities for graduate study in agriculture in the United States, A. C. Monahan (Buv. of Ed. [U. S.] Bul. 2, 1911, pp. 16).—This bulletin has been noted editorially (E. S. R. 25, p. 705).

Agicultural and forestry education in Austria] (Land u. Forstw. Unterrichts Ztg., 24 (1910), No. 1-2, pp. V+147+IXIII).—This report includes special articles on The Didactic and Pedagogical Trend of Natural Science Instruction in Agricultural Schools, by Josef Röschen: Commercial Instruction in Agricultural and Forestry Schools: The Present Social Pedagogical Agencies, by Ludwig Fleischner; This Year's Course of Study for Itinerant Agricultural Instructors in Eisenach, by Hans Albrecht; and statistical tables and other data relative to the organization, curriculum, attendance, graduates, etc., of the agricultural and forestry educational institutions in Austria.

The statistics show that in March, 1910, there were 214 agricultural and forestry educational institutions in Austria, an increase over 1909 of 1 farm school, 3 agricultural winter schools, and 4 domestic science schools. The 214 institutions include 1 agricultural high school, 2 agricultural high school sections, 3 agricultural academies, 1 brewing academy, 9 agricultural and 5 forestry high schools, 2 high schools for viticulture, fruit culture and horticulture, 42 farm schools or elementary agricultural schools with a one-year course, 85 agricultural winter schools, 11 elementary forestry schools, 21 dairy and housekeeping schools, 28 elementary special schools for horticulture, viticulture, fruit, vegetable, flax, hop, meadow, and alpine culture, and apiculture, and 2 brewing and 2 distillery schools.
[Agricultural and forestry education in Austria] (Land u. Forstw. Unterrichts Ztg., 24 (1910), Nos. 3-4, pp. 119-311).—This report includes among other data the following special articles: The Mutual Assistance of the School and Home in Agricultural School Life, by Franz Kozeschnik; Concerning the Education of the People Outside of School, by Ludwig Fleischner; The Introduction of Agricultural Courses into the Army; The Cultural Significance of Instruction in Home Economics, by Franz Brosch; The Text-book Question, by Ernst Vital; Concerning Several Public and Private Economic Problems of Forest Production, by Adolf Cieslar; The Determination of Subject-matter in Lower Forestry Instruction, by Karl Pusch; and Commercial Instruction in the Agricultural and Forestry Schools and Itinerant Domestic Science Schools in France, by Leopold Freih. v. Hennet.

Housekeeping instruction for girls in Prussia, L. Axt (Monatsh. Landw., 4 (1911), No. 7, pp. 293-310).—This is a discussion of the need of housekeeping instruction in Prussia, followed by a detailed account of the agencies by means of which this instruction is being given in rural communities, such as permanent agricultural housekeeping schools and itinerant courses, as well as the training of teachers for this work.

Instruction in the practical agricultural schools, J. J. Barneda (Min. Agr. [Argentina], Div. Enseñanza Agr. [Pub.], 5. ser., 1910, No. 1, pp. 32).—This is a detailed statement of the object of the practical schools of agriculture in Argentina, together with information concerning students, faculty, courses of study, methods of instruction, etc.

Carrying the message to the people, E. E. Sparks (Farmers' Nat. Cong. U. S. Proc., 30 (1910), pp. 55-58).—The author outlines the various methods suggested by teachers and investigators to keep the boy and the girl on the farm and concludes that the solution of the problem lies in education. He reviews the differing requirements for country and city life, and states that whether the endeavor to teach agriculture in the public schools will be more than an attempt will depend upon the training of the teacher to teach the subject efficiently, upon convincing the teacher that the subject can be taught successfully, and upon providing the teacher with a more serviceable outfit than the text-book.

Elementary school agriculture, E. B. Babcock and C. A. Stebbins (New York, 1911, pp. 65, figs. 8).—This is a teacher's manual to accompany Hilgard and Osterhout's Agriculture for Schools of the Pacific Slope (E. S. R., 25, p. 207). It contains suggestions for school gardens and also for the development of typical lessons. In connection with these suggestions there are directions for setting up and using apparatus and other illustrative material. Appendixes contain an outline of agriculture and nature study by groups, lists of plants requiring comparatively large amounts of water and comparatively little water, and lists of reference books and other publications.

The school garden in the course of study, E. B. Babcock and C. A. Stebbins (California Sta. Circ. 62, pp. 12).—A progressive course in school garden work is outlined in the first half of this circular from the first to the eighth grade, with a group scheme for smaller schools. The balance of the circular presents a course of study in school gardening for the sixth, seventh, and eighth grades.

Boys' corn clubs and improved methods of corn growing, T. R. Bryant (Kentucky Sta. Bul. 153, pp. 3-15).—This bulletin is designed to meet the needs not only of the members of the boys' agricultural clubs but also of farmers in general. A general outline is given for a proposed constitution and by-laws for boys' agricultural clubs and of the principal points to be considered by such clubs. A brief general discussion is included on fertilizers, the importance of
good seed, how to select and preserve seed corn, the germination test, grading by the size of the grains, the preparation of the seed bed, planting and cultivation, judging corn, and the standard ear. There is also a corn score card, as adopted by the Kentucky corn growers' association and a list of bulletins of the Kentucky Station available for distribution.

How to make an observation hive, L. J. Nickels (California Sta. Circ. 63, pp. 13, figs. 4).—The purpose of this circular is to aid the student to a better understanding of the colony life of honeybees as an example of perfected cooperation. An observation hive for schoolroom use is described and drawings and specifications are reproduced. A bibliography suggests publications of this Department on bee keeping, standard works, bee magazines, and popular works.

University Farm School, Davis, Cal. (California Sta. Circ. 61, pp. 19, figs. 7).—This is the 1911-12 announcement for the school.

Announcement of farmers' short courses for 1911 (California Sta. Circ. 64, pp. 16).—This is an announcement of farmers' short courses for 1911 at the University Farm, Davis, Cal.

MISCELLANEOUS.

Thirty-third and Thirty-fourth Annual Reports of Connecticut State Station, 1909-10. (Connecticut State Sta. Rpt. 1909-10, pl. 12, pp. XX).—These pages include the organization list; a report of the board of control, in which are embodied resolutions adopted regarding the life and work of the late S. W. Johnson, a former director of the station; a financial statement for the fiscal years ended September 30, 1909, and September 30, 1910; and a list of corrections to the report.

Twenty-third Annual Report of Louisiana Stations, 1910 (Louisiana Sta., Rpt. 1910, pp. 27).—This contains the organization list, a report of the director, and departmental reports on the work of each of the stations, lists of publications issued during the year, and a financial statement as to the federal funds for the fiscal year ended June 30, 1910, and as to the state funds for the fiscal year ended November 30, 1910.

Annual Report of Porto Rico Station, 1910 (Porto Rico Sta. Rpt. 1910, pp. 44, pls. 4).—This contains the organization list, a summary by the Special Agent in Charge of the investigations conducted at this station during the year, and separate reports by the physiologist, chemist, horticulturist, entomologist, pathologist, coffee expert, assistant horticulturist, and animal husbandman. The experimental work reported is for the most part abstracted elsewhere in this issue.

The report of the chemist includes analyses of soils from a citrus grove, goat manure, sheep manure, seaweed, cachasa (filter press residue), burnt lime, and disintegrated limestone, and data on an experiment showing an increased yield of sugar cane following the use of lime and a complete fertilizer.

Monthly Bulletin of the Department Library, July, 1911 (U. S. Dept. Agr., Library Mo. Bul., 2 (1911). No. 7, pp. 187-206).—This number contains data for July, 1911, as to the accessions to the Library of this Department and the additions to the list of periodicals currently received.

Changes in inspection laws (Maine Sta. Off. Ins. 32, pp. 65-76).—This publication points out the changes in and the chief requirements of the various Maine laws relating to the inspection of agricultural seeds, fertilizers, feeding stuffs, foods, drugs, fungicides, and insecticides as amended at the 1911 session of the legislature. Directions for sampling materials for free analysis by the station are appended.
NOTES.

Connecticut State Station.—The station has designed an educational exhibit to show the departments of work in which it is engaged, and also something of methods and results. The exhibit fills a tent 40 by 60 feet, owned by the station, and has been set up at five or six of the agricultural fairs in the State. Members of the station staff are in daily attendance to explain the exhibit and answer questions. All labels are printed, and special study has been given to make them as plain and instructive as possible. The exhibit has attracted much attention wherever shown.

Georgia College.—The last legislature increased the appropriation for extension work from $12,500 to $15,000 and the college maintenance fund by $10,000, making for the ensuing biennium an income of $250,000 for the furtherance of education in agriculture and extension teaching. It is hoped to inaugurate extension work on soils, organize breeding work with corn and cotton throughout the State, enlarge the work with boys and girls through the schools, foster animal and poultry husbandry through the establishment of special extension departments, and greatly enlarge the organization of itinerant schools of agriculture. The attendance in the college has increased in a gratifying manner.

An appropriation of $5,000 has been granted for the manufacture of hog cholera serum, of which $3,000 is for the equipment of the plant. The serum is to be sold by the state veterinarian at cost and the receipts revert back to the veterinary department of the college for subsequent maintenance.

Idaho University and Station.—The university has completed a live-stock judging pavilion for the use of classes in animal husbandry. This is a one-story structure, 36 by 60 feet, in mission style, with stucco finish on the outside, with raised seats, wide roomy space for live-stock specimens, and equipped with a heating plant, an office, and stall room for stock.

There has also been completed a modern dairy and live-stock barn for the use of the college and station. The main part of this barn has two floors, and is 48 by 66 feet in size, with a concrete silo 33 by 16 feet. There is also a wing for dairy stock 36 by 55 feet, provided with a milk room, an office, and complete equipment.

Recent appointments include the following: E. W. Hamilton as professor of agricultural engineering, Dr. E. T. Baker as professor of veterinary science, C. E. Temple as associate professor of agricultural botany and plant pathology, Cecil Starring as assistant in horticulture in the college and assistant horticulturist in the station, and C. V. Schrack, as gardener.

Purdue University.—A bequest to the school of agriculture of $50,000 and 1,500 acres of Minnesota land by the late William C. Smith, of Williamsport, Ind., is announced.

The entering class in agriculture is 137, a 20 per cent increase over last year and the largest in the history of the institution.

The farmers' short courses this year are to be shortened from a week to three days, and they are to be held in the smaller rural towns rather than in the larger cities, as in the past. Nearly 30 applications have already been received.
Iowa College and Station.—A two-story octagonal pavilion, 65 feet in diameter and of pressed brick, is being erected for the farm crops and animal husbandry laboratory work at an estimated cost of $17,000. It is to be connected with one of the other pavilions used for similar work.

H. B. Potter has resigned as assistant professor of farm crops to become associate editor of Farm and Fireside. H. B. Kinney has been appointed research laboratory assistant in soil chemistry.

Kentucky Station.—The foundation for an addition to the present station building, to cost $50,000, is under construction. This addition will be larger than the present structure but otherwise practically a duplication. The chemical laboratories and the bacteriological, food, and feedstuffs work will be located in the new portion when completed.

Massachusetts College.—Extension schools of agriculture and domestic science are announced for the first time. It is planned to hold not to exceed one in each county, each to last 5 days and local expenses to be met by the community.

The correspondence courses are proving increasingly successful and a course in shade-tree management is to be added. The college is again cooperating with the Springfield Y. M. C. A., which is arranging eight lecture courses in agriculture, horticulture, landscape gardening, beekeeping, poultry keeping, and dairying. The lectures are to be held in Springfield but the college furnishes all speakers.

Active cooperation has also been given to the first State corn show, which was recently held in Springfield and was very successful.

Minnesota University and Station.—According to the University Farm Press News, the Minnesota State Department of Public Instruction and the extension division of the university are cooperating in a systematic effort for the introduction of agriculture into the rural schools this year. A special monthly leaflet from the extension division, called Rural School Agriculture, is being sent to every rural school teacher in the State, with the idea of interesting thereby the boys and girls each month in those things which are being done on the farm and in the home during that month. Tests to be conducted at home and the reports brought to school for discussion are suggested.

D. A. Gaumnitz, assistant animal husbandman, and John Spencer, assistant in veterinary science and veterinarian, have resigned to engage in commercial work. R. H. Williams has been appointed assistant professor of animal husbandry in the university and assistant animal husbandman in the station. Dr. B. A. Beach, research assistant in veterinary science in the station, has resigned and is succeeded by Dr. W. L. Boyd. Johann Dittman has been appointed in charge of the denatured alcohol plant and William Underwood investigator in wood preservation. E. C. Huntington has resigned as editor in agricultural extension and farmers' institutes.

Missouri University and Station.—Two new buildings, a veterinary building and an implement building, have been added during the past summer. The veterinary building is a stone structure, three stories high, 120 feet long and 60 feet wide. It contains two large operating rooms, a dissecting room, a large lecture room, two large laboratories, and several smaller ones and offices. The implement building is 30 by 80 feet, and is divided into eight compartments.

The State Board of Horticulture is offering a prize of a $50 scholarship in the short course to the boy selecting and sending in the best half peck of apples, together with a paper setting forth why he chose the variety selected and what treatment the trees have received in the way of cultivation, spraying, pruning, etc. The fruit sent in will be kept in cold storage and later exhibited at fruit
shows and expositions which may be held by the board. Similar prizes are also offered by the state fair management to the young men showing the greatest proficiency in judging live stock, corn, and poultry products at the fair.

An appropriation of $5,000 has been made by the state legislature for carrying on extension work.

Plans have been formulated for holding several branch short courses in agriculture at various points in the State during the coming winter. At each of these the college of agriculture will furnish two men who will give instruction in agriculture for five days. Local expenses are to be defrayed by the community and a guaranteed attendance of at least 20 students will be required.

B. Szymoniak, a 1910 graduate of the university, has been appointed assistant in horticulture, and has entered upon his duties.

New Hampshire College and Station.—Beginning with November the extension department is planning to issue each week a press bulletin on some timely topic related to agriculture. These press bulletins will be sent to the station mailing lists within the State.

New Mexico College and Station.—J. H. Squires, J. E. Mundell, H. H. Schutz, and José Quintero have resigned to accept positions elsewhere. New appointments include the following assistants: R. L. Stewart and T. W. Conway in agronomy, J. W. Rigney and S. E. Merrill in horticulture, D. E. Merrill in entomology, and G. R. Quesenberry in animal husbandry. Dr. Eugene P. Humbert, associate biologist of the Maine Station, has been appointed agronomist.

Ohio State University.—Registration in the college of agriculture and domestic science has reached 863, making this the largest college in the university, with a gain of 281 over 1910.

Oklahoma College and Station.—L. G. Griffin has succeeded Frank Ikard on the governing board. The position of assistant director of the station has been discontinued, and B. C. Pittuck has been made dean of all extension work of the college. Recent appointments include J. E. Payne, of the Colorado Station, to take charge of the Adams fund work in plant breeding for drought resistance at the Goodwell substation; A. A. Jones, of the Missouri University and Station, as assistant station chemist; T. E. McElroy, recently engaged in commercial work with insecticides, as assistant entomologist, vice A. L. Lovett, whose resignation has been recently noted; B. J. Clawson as assistant in zoology and veterinary science, vice W. S. Robbins, resigned to accept a similar position at the Michigan College and Station; and J. M. Cadwallader as assistant in dairying.

Oregon College and Station.—E. R. Stockwell has been appointed research assistant in dairy husbandry.

Pennsylvania College and Station.—Recent appointments include the following: Reginald R. Chaffee, of the Forest Service, as instructor in forestry; C. A. Smith and A. B. Werby as assistants in agricultural chemistry; W. R. White as instructor in agricultural education; Frank App as assistant in agronomy; and Ferdinand A. Varrelman as instructor in zoology.

Porto Rico University.—Dr. F. L. Stevens, of the North Carolina College and Station, has accepted the position of dean of the college of agriculture, and expects to begin its organization January 1, 1912. The establishment of a tropical botanical and zoological laboratory is contemplated in connection with the college.

Clemson College and Station.—W. R. Perkins, director of the department of agriculture of the college and professor of agronomy, resigned November 1 to take charge of a syndicate farm in Mississippi. C. S. Lykes is no longer connected with the station. L. D. Boone has been appointed assistant in chemistry.
Tennessee Station.—A special train has been sent out through east Tennessee, through the cooperation of the college and station, the state department of agriculture, the state board of health, and the Southern Railway Co. It contained four demonstration cars for live stock, agricultural and horticultural products, and exhibits relating to health and educational subjects. About 20 experts accompanied the train, and stops of one day each were made at about 30 different county seats.

Utah Station.—L. M. Winsor has been appointed assistant irrigation engineer.

West Virginia University.—A department of agricultural education has been established in the college of agriculture, with A. W. Nolan as associate professor of agricultural education at its head. It is planned, among other things, to publish (1) a monthly bulletin on school agriculture, (2) bulletins on nature study for teachers of grades below the seventh, and (3) to cooperate with the county superintendents and teachers in promoting boys' and girls' corn-growing contests.

C. R. Titlow, assistant in agricultural extension work at the Ohio State University, has been appointed director of agricultural extension, to take effect January 1, 1912.

Wisconsin University and Station.—The facilities of the poultry department have been increased by the construction of a fattening shed, 16 by 32 feet, which will be used in part for pen feeding and in part for crate fattening. For the present, work conducted in this building will be instructional in character, but it is hoped at a later date to take up experimental work. The department is also constructing 15 colony houses, which will be used for research work along the lines of breeding and nutrition.

Canadian Experimental Farms.—An additional farm has been established at Scott, Saskatchewan, in charge of R. E. Everest, and others at Kentville, Nova Scotia, and Wilmer, British Columbia. T. H. Moore has succeeded Thomas Sharp as superintendent of the farm at Agassiz, British Columbia, and W. C. McKillican has succeeded James Murray at Brandon, Manitoba. W. W. Thomson has been appointed assistant at Indian Head, Manitoba.

Porto Rico Board of Agriculture.—The Porto Rico Board of Agriculture was organized June 16 with headquarters at San Juan. Its contemplated duties are the inspection and quarantine of imports with a view to the exclusion of noxious pests, the introduction of beneficial birds, parasites, etc., the enforcement of protection for birds, and control regulations as to plant and animal pests, scientific work relating to these lines, and educational work, as by compiling and publishing data, preparing school exhibits, etc.

The construction of three fumigation houses has been authorized and W. V. Tower, of the Porto Rico Federal Station, appointed entomologist of the board to enforce the quarantine against importations, as previously noted. C. E. Hood, of the Bureau of Entomology of this Department, has been appointed to undertake the introduction into Porto Rico of natural enemies of the white grub. Arrangements are also being made for a survey of the birds and forestry resources of the island and of the measures advisable for their development and for the collection of agricultural statistics.

Agronomic-geological work in Germany.—At a recent meeting of the German Agricultural Council two addresses were delivered bearing on the present status of the geological-agronomical investigations in Germany and their application to agriculture. The sentiment of the meeting is summed up in the following recommendations, which were indorsed at the meeting.

(1) Soil studies, and other investigations the results of which may be influenced by the nature of the soil, should give attention to the soil profile and the underground geology.
(2) An early completion of the geological surveys on a scale of 1:25,000 is very urgent in all the German States in order that the present generation may receive the benefits therefrom.

(3) In addition to the general geological maps there should also be prepared smaller maps for use of state and agricultural societies, as well as for the benefit of estates.

(4) Schools of agriculture and forestry have a special obligation in the maintaining of courses of instruction in soils on a geological basis. Soil science should be taught by men well grounded in a knowledge of practical geology.

(5) It would be a grateful function of the agricultural societies to correlate farm practice with the teachings of the geological maps in order that their agricultural value might be enhanced.

Sixth National Dairy Show.—According to the Breeder’s Gazette, “the magnitude and might of the Sixth National Dairy Show set a milestone in the progress of the industry.” This show took place in the International Live Stock Exposition Amphitheater in Chicago, October 26 to November 4. Over 1,000 of the leading dairy breeds were shown. The exhibits of dairy machinery and appliances excelled those of previous years, and federal, state, and city governments were strongly represented as to their work in connection with the dairy industry. Unusual prominence was accorded the enterprise by the daily press of Chicago, and the attendance was gratifying as compared with previous years.

A noteworthy feature of the show was the attendance of the President of the United States, who gave a brief address in which he commended the scope and purpose of the enterprise and emphasized the necessity of adopting improved farming methods and breeding more efficient dairy stock as a means of keeping pace with the requirements of the increasing population. The President also offered a silver cup to the student making the highest score in the dairy stock judging contest, and presented this cup in person to the winner, Russell Jensen, of the South Dakota College.

The students’ judging contest attracted much attention, teams from 10 institutions competing. As in previous years, valuable trophies and individual scholarships were offered by the various breeders’ associations and others. The Kentucky University team won first place, with Ohio State University second, and South Dakota third. The Maryland College won first place in judging Ayrshires and Jerseys, and Kentucky on Guernseys and Holsteins.

First International Dairy Show.—This enterprise was held at Milwaukee, October 10–18, with an excellent attendance throughout. The opening address was by Secretary Wilson of this Department.

Among the features of the show were the 500 entries of dairy stock, the extensive machinery exhibits, a model creamery operated by the Dairy Division of this Department, a cheese factory fitted up with modern machinery, the interstate butter contest, a demonstration herd showing groups of cattle fed in different ways, a child-welfare exhibit, and illustrative material from the Milwaukee Health Department and the University of Wisconsin. Among other awards were those to herdsmen for ability in fitting and showing cattle, neatness of person, and herd quarters.

Sixth International Dry-Farming Congress.—The Sixth Dry-Farming Congress was held at Colorado Springs, Colo., October 16–20, with a large and representative attendance, including delegates from Canada, Mexico, Central and South America, England, France, Germany, Austria, Russia, Africa, India, China, Japan, and Australia. A varied program was presented, including extensive exhibits of crops produced under dry-farming conditions.
The presidential address was given by President J. H. Worst, of the North Dakota College and Station, who advocated additional funds for the study of dry-farming methods. Other addresses were by H. L. Bolley, of the North Dakota College and Station, on flax as a dry-farming crop, and Director E. H. Webster, of the Kansas College and Station, who advocated a wider use of live stock and forage crops. President John A. Widtsoe, of the Utah College, was chosen president for next year, when the congress will be held at Lethbridge, Alberta.

The First International Congress of Farm Women was held in conjunction with the congress. Among the speakers was Mrs. Mary P. Van Zile, of the Kansas College, who discussed food values.

Farmers' National Congress.—At the thirty-first session of this organization, held at Columbus, Ohio, October 12-16, George M. Whitaker, of the Dairy Division of this Department, was elected president. Among the speakers were Assistant Secretary W. M. Hays, of this Department, on Possibilities of Advancement in American Agriculture; G. I. Christie, of Purdue University, on Extension Work of Agricultural Colleges; Acting Dean Vivian, of Ohio State University, on To What Extent have Agricultural Colleges Improved Agriculture; C. S. Plumb on Animal Industry for Meat Supply; and Miss Ruth A. Wardall on Woman and the Home.

South American Congress of Agricultural Sciences.—Pursuant to a resolution of the International Scientific Congress, a South American Congress of Agricultural Sciences will be held in Buenos Aires in July, 1913. The organization of the congress is intrusted to the Argentine Rural Society, the National Society of Agricultural Engineers, and the National Schools of Agriculture of Buenos Aires and La Plata.

Agricultural Instruction in the Austrian Army.—The first attempt in Styria to give instruction in agriculture to soldiers was a course offered from November 16, 1910, to May 19, 1911, at Marburg. The instruction was given by two teachers of the Royal Fruit and Viticultural School. Forty hours were devoted to lectures at the barracks, and 8 hours to practical demonstrations on the school farm. Twenty-five soldiers voluntarily attended the course with great interest.

Miscellaneous.—The Rev. Henry C. McCook, LL. D., D. D., D. Sc., well known for his entomological writings, died October 31 at his home in Devon, Pa., at the age of 74 years. Dr. McCook was for many years an active member of the Philadelphia Academy of Natural Sciences, serving at one time as vice president. He also served as president of the American Entomological Society and was an honorary member of the British Museum. His principal entomological works are The Agricultural Ants of Texas, The Honey and Occident Ants, American Spiders and Their Spinning Work, and Tenants of an Old Farm.

Lord Carrington has retired as president of the Board of Agriculture and Fisheries in Great Britain, and has been succeeded by Walter Runciman, formerly minister for education. Lord Lucas becomes parliamentary secretary of agriculture in succession to Sir Edward Strachey.

Hon. Martin Burrell, who has been a practical fruit grower of British Columbia for several years, has been appointed minister of agriculture for the Dominion of Canada.

Dr. O. S. Morgan has been appointed professor of extension teaching in agriculture in Columbia University.

Note.—The price of *Experiment Station Record* is $1 per volume, and two volumes are issued annually. It may be purchased from the Superintendent of Documents, Washington, D. C., to whom all remittances should be made. The publications of the State experiment stations are distributed from the stations and not from the Department.
ILLUSTRATION.

EXPERIMENT STATION RECORD.

Vol. XXV. Abstract Number. No. 9.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Vegetable fats and oils, L. E. ANDÉS, trans. by C. SALTER (London, Toronto, and New York, 1902, 2. ed., cul., pp. XVI+3½, figs. 9½).—This publication, which deals with the practical preparation, purification, properties, adulteration, and examination of vegetable fats and oils, contains data as to the estimation of the amount of oil in seeds; the preparation of vegetable fats and oils; apparatus for grinding oil seeds and fruits; nondrying and drying vegetable oils; solid vegetable fats; seeds and fruits yielding oils and fats; soluble oils; improved methods of refining with sulphuric acid and zinc oxide or lead oxide, with caustic alkalis, ammonia, carbonates of the alkalis, and lime, or with tannin; Ekenberg's method of refining; Villon's process for purifying oils by sulphurous acid; mechanical appliances for refining; Filbert's deodorizing apparatus for oils and fats; bleaching fats and oils; practical experiments on the treatment of oils with regard to refining and bleaching; oil cake and oil meal; testing oils and fats; maize oil: fatty acids of coconut oil; and vegetable tallow from the Dutch East Indies.

Composition of rice oil, M. TSUJIMOTO (Chem. Rev. Fett u. Harz Jadus, 18 (1911), No. 5, pp. 111, 112; abs. in Ztschr. Angew. Chem., 2½ (1911), No. 29, p. 1386).—Rice oil is usually obtained by extracting rice bran with petroleum ether. It is fluid and has a greenish yellow color. The unsaponifiable part (4.78 per cent) is probably composed of phytosterin. The fatty acids are chiefly palmitic, oleic, and isoeleic acids, and if the amount of solid fatty acids is taken as 20 per cent, and the iodin number of the liquid acid as 130, they can be considered proportionately as follows: Palmitic acid 20 per cent, oleic acid 45 per cent, and isoeleic acid 35 per cent.

In regard to the refraction constants of vegetable oils, J. KLIMONT (Ztschr. Angew. Chem., 2½ (1911), No. 6, pp. 25½-256).—The oils examined were rape, cotton-seed, linseed, corn, olive, soy-bean, soy-bean in a mixture with cotton-seed, sesame, peanut, hedge mustard, and neats-foot oils, in regard to their density, refraction exponent, specific refraction, saponification number, iodin number, and middle molecular refraction. The work was done with particular reference to the last-named constant.

Reactions of carbohydrates.—I. Sucrose, C. REICHARD (Pharm. Zeitschrift, 51 (1910), pp. 979-986; abs. in Jour. Chem. Soc. [London], 98 (1910), No. 578, II, p. 1117).—This work with solid sucrose shows that in the cold, sulphuric acid, nitric acid, or hydrochloric acid convert this sugar into a pasty mass, which does not dry in the air. Carbonaceous matter produced with sulphuric acid did not separate until the mixture was heated.

801
The green coloration of copper sulphate in hydrochloric acid is retained much longer when sucrose is present, and it inhibits somewhat the precipitation produced by hydrochloric acid when added to mercurous nitrate. In the presence of hydrochloric acid sucrose yields a dark green coloration with potassium bichromate, a blue with ammonium molybdate, and a brown, which changes to violet, with ammonium vanadate. No coloration was produced with sodium tungstate or titanic acid in the presence of sulphuric acid. Sodium arsenate and hydrochloric acid together with sucrose produce a rose-red color. Of the colorations produced with organic bodies the most marked is the red with tannic acid in the presence of hydrochloric acid. Resorcin and hydrochloric acid gave a gooseberry-red color. The author points out the value of the last two and of the arsenic acid reaction for the detection of sucrose.

Behavior of humin in alkaline solutions of bromin, A. Konschegg (Ztschr. Physiol. Chem., 69 (1910), No. 5, pp. 390–394).—Humin bodies were prepared by treating carbohydrates as follows:

Two hundred and fifty gm. of dextrose were heated for 12 hours with 1 liter of 24 per cent hydrochloric acid solution, the latter being repeatedly evaporated off and replenished. The resulting dark brown brittle mass was extracted with potassium hydrate, it being only partly soluble. The resulting filtered brown solution when treated with dilute hydrochloric acid yielded a brown flocculent precipitate. This precipitate was considered humic acid, and the portion insoluble in potassium hydrate, humin.

The insoluble humin when repeatedly treated with a warm potassium hydrate solution was converted into a slimy, tough mass. This mass was repeatedly washed with water to remove the alkali, and dried at 100° C. to a hard, vitreous-like brittle mass, which when ground yielded a brown powder insoluble in water, alkali solutions, acids, ether, and alcohol. It was, however, found to be soluble in an alkaline bromin solution, but only when the mass was mixed with the potassium hydrate solution first and bromin added slowly afterwards. After a time some white flocculent matter was precipitated. The same kind of precipitate was also obtained from the humic acid, and when examined under the microscope was found to be crystalline in structure. It was readily soluble in ether. The crystals were finally obtained in a pure state, and were found to possess a melting point of 92°, to be readily soluble in ether, acetone, and chloroform, and to have a camphor-like irritating odor. On the basis of analysis the author believes it to be tetrabromomethan.

This work indicates that carbohydrates are not totally decomposed by the action of acids.

A study of the lignocellulose of timothy hay, G. C. Given (Pennsylvania Sta. Rpt. 1910, pp. 248–254).—The lignic acid, so-called, present in timothy hay (Phleum pratense), was found to resemble the lignone which has been obtained from jute and the lignin obtained by Browne (E. S. R., 16, p. 440) from sugar-cane fiber. It had a dark brown color and a vanillin-like odor. It was found to have an active carbonyl of ketone nature and an active carboxyl group, as evidenced by the fact that the precipitate gave reactions with semi-carbazid and with nitrate of silver. Aldehyde could not be obtained with Schiff's reagent. It was not determined whether the body belonged to the hexene series, in which it was placed by Cross and Bevan, but if so the author suggests that it has one or more side chains in view of its behavior with potassium permanganate. An elementary analysis of the lignin precipitate gave a formula corresponding to C_{28}H_{39}O_{18}.

Cellulose when prepared by the usual methods was found to contain much oxycellulose. Phleum, the inulin-like body observed by Ekstrand and Johanson
in the nodules of timothy hay, could not be noted by the author in a watery extract of the hay.

The production of acetic and formic acid by hydrolyzing substances containing lignin, W. E. Cross (Ber. Deutsch. Gesell., 43 (1910), No. 8, pp. 1526-1528; abs. in Ztschr. Untersuch. Nahr. u. Genussmittel, 21 (1911), No. 11, p. 679).—By hydrolyzing jute, wood, or straw, etc., with a 1 per cent sulphuric acid solution at 110° C., evaporating the extract neutralized with calcium carbonate in a vacuum, and distilling in a stream of steam, from 1.2 to 2.8 per cent of acids (acetic and formic) are obtained. From pine wood the proportions were 4 parts of acetic to 1 part of formic acid. The acids did not originate from the cellulose, and according to the author lignin is the probable source.

"Sugar sand" from maple sap; a source of malic acid, W. H. Warren (Jour. Amer. Chem. Soc., 33 (1911), No. 7, pp. 1205-1211).—Maple sap from Acer saccharum, when evaporated, deposits a variable quantity of the calcium salt of malic acid, which goes under the name of either niter or sugar sand. With care, from 16 to 25 lbs. of this substance can be obtained from about 1,000 trees per season. While this substance has already been examined by others (E. S. R., 12, p. 78), the author points out that the results were obtained with material which was not exactly typical. The analysis which follows is said to represent within narrow limits the quantities of the several constituents which this by-product may be expected to contain: Silica 7.74, phosphoric acid 0.05, ferric oxid 0.39, calcium 17.16, magnesium 0.03, moisture 2.6, malic acid 51.48, invert sugar 2.31, cane sugar 3.46, ether soluble matter 0.37, carbon dioxid 0.66, extraneous organic matter 2.35, undetermined (by difference) 11.4 per cent.

A method for obtaining malic acid is appended.

In regard to the fixation of lactic acid by casein, W. van Dam (Chem. Weekbl., 7 (1910), No. 49, pp. 1013-1019).—The author in this work determined the variation in the hydrogen ion concentration of lactic acid caused by the addition of casein. When a twentieth-normal solution of lactic acid was employed for varying quantities of casein at a temperature of 18° C., it was noted that as long as an excess of hydrogen ions was present in the solution the amount of lactic acid bound was constant. With very large quantities of casein, however, this relation was destroyed, and the amount of acid bound was very much less.

Protective enzymes [in fruits], M. T. Cook et al. (Science, n. ser., 33 (1911), No. 831, pp. 624-629).—In this preliminary paper the authors point out "that there exists in the normal living fruit two enzymes, a catalase and an oxidase.

"The latter is probably most abundant in the early part of the season, gradually decreasing in activity as the fruit approaches maturity and ripens. Furthermore, from the results it appears that tannin as such does not exist in any part of the normal, uninjured fruit previous to maturity, except possibly a small amount in the peel, but exists as a poly-atomic phenol, which upon injury is acted upon by the oxidase and forms a tannin or tannin-like body having the property of precipitating protein matter, and at the same time forming a germicidal fluid. This oxidase acts only in an acid solution and when present in an amount above a certain undetermined minimum. The above conditions are always present in normal immature pomaceous fruits. When normal, immature fruits are subjected to injury by fungi, insects, or mechanical agencies, the action of the oxidase on poly-atomic phenols is brought about with the effects as stated above."

Tests with the diastase of Aspergillus oryzae, F. Münter (Landw. Jahrh., 39 (1910), Ergänzungsb. 3, pp. 298-314).—The results of this work show that (1) alcohol and ether destroy the activity of this enzym; (2) ammonium sul-
phate is the only substance with which this enzym can be salted out (potassium chloride, potassium sulphate, sodium chloride, sodium sulphate, sodium phosphate, potassium phosphate, ammonium nitrate, magnesium chloride, magnesium sulphate, calcium nitrate, and zinc sulphate could not be used); (3) the nitrogen content of the various precipitates is no criterion in regard to the activity; (4) no diastatic enzym could be separated by dialyzing through parchment paper; (5) small additions of sugar to enzym solutions have no effect upon the hydrolytic process, but a large amount of maltose (Saccharification products), on the other hand, inhibits the process; (6) the optimum and lethal temperatures of diastase of different origins are different; (7) the diastatic capacity of diastase which has been weakened by heat can be increased by certain additions, such as sodium chloride and egg white, peptone, or asparagin; and (8) the Hamburg and Fränkel chemical-biological method for the precipitation of diastases is not efficient.

Modification of the diphenylamin test for nitrous and nitric acids, W. A. Withers and B. J. Ray (North Carolina Sta. Rpt. 1910, pp. 56–58).—Combining some of the features of the different methods the authors have prepared a reagent which in their hands has proved to be very delicate. It is made as follows:

"Seven hundred mg. of diphenylamin are dissolved in a mixture of 60 cc. of concentrated sulphuric acid and 28.8 cc. of distilled water. The resulting mixture is thoroughly cooled and 11.3 cc. of concentrated hydrochloric acid (specific gravity 1.19) are added slowly—making the hydrochloric acid content 5 per cent. After standing over night some of the base separates showing that the reagent is saturated. The test with the diphenylamin reagent as prepared by the authors is conducted as follows: Place 1 cc. of the liquid to be tested in a clean test tube; add 1 drop of the diphenylamin reagent and mix thoroughly by shaking. From a pipette is added 2 cc. of concentrated sulphuric acid, while the tube is held at an angle so as to form 2 layers of the liquids. The tube is gently agitated so as to cause a slight mixing of the liquids at the plane of contact, and it is then placed in a bath at the temperature of 40° and left for 15 or 20 minutes. This method will reveal the presence of 1 part of nitrite nitrogen in 25,000,000 or 1 part of nitrate nitrogen in 35,000,000. By heating for 1 hour instead of 15 or 20 minutes the test will show 1 part of nitrite nitrogen in 32,000,000 or 1 part of nitrate nitrogen in 44,000,000."

Test for nitric acid. F. Klein (Jour. Indus. and Engin. Chem., 2 (1910), No. 9, p. 389; abs. in Jour. Soc. Chem. Indus., 29 (1910), No. 20, p. 1200).—The reagent used in this test is made by adding a little powdered tellurium to from 2 to 3 cc. of fuming sulphuric acid, and then from 1 to 2 cc. of 95 per cent sulphuric acid.

When a little of a nitrate or strong nitric acid is added to the reagent and heated, the eosin-red color which the reagent possesses is discharged. When dilute nitric acid (less than 40 per cent) is present, it is neutralized and the solution is evaporated to dryness before the test is complete. It was found that a solution consisting of 0.1 gm. of tellurium in 10 cc. of fuming sulphuric acid and 10 cc. of 95 per cent sulphuric acid is decolorized by 0.66 gm. of 66 per cent nitric acid.

The use of the above principle as a basis for quantitative colorimetric tests is pointed out.

The method has for its principle the interaction of nitrates and anhydrous formic acid, and proceeds according to the following equation:

\[ 2\text{KNO}_3 + 6\text{H}_2\text{CO}_3 \rightarrow \text{N}_2 + 4\text{CO}_2 + 5\text{H}_2\text{O} + 2\text{H}_2\text{CO}_3\text{K}. \]

Analysis of calcium cyanamid, A. Stutzer (Chem. Ztg., 35 (1911), No. 76, p. 694; abs. in Jour. Soc. Chem. Indus., 30 (1911), No. 4, p. 312).—The results of determining the total nitrogen in calcium cyanamid by the Kjeldahl method were found to agree well with those obtained by the salicylic acid method. This is contrary to Monnier's findings, who obtained results 1 per cent too low with the former method. Only 0.14 per cent of nitrogen instead of 1.52 per cent, as stated by Monnier, was found to be derived from the carbon used in the manufacturing process.

The use of silver phosphate as a standard for phosphoric acid, and a critical study of the gravimetric magnesium method for the estimation of phosphoric acid, W. C. Dumas (Chem. Engin., 12 (1919), No. 6, pp. 185–190, fig. 1; abs. in Chem. Ztg., 35 (1911), No. 18, Repert., p. 65).—As the controlling substances of these determinations the author utilized silver phosphate, and as a result of the work he points out that the composition of magnesium ammonium phosphate may vary to a considerable extent. The proper composition, however, may be obtained when the precipitation is made from a neutral solution. The precipitate obtained from a weakly alkaline solution was found to be high in phosphoric acid and low in magnesium; some of the phosphoric acid is volatilized on ignition. In rapidly precipitating from a neutral or slightly alkaline solution the phosphoric acid content of the precipitate is low and the magnesium high. Magnesium pyrophosphate must be heated for at least 1/2 hour. Magnesium ammonium phosphate loses water and ammonia at 100° C.

Detection of arsenic acid in the presence of phosphoric acid, G. Madeena (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. c Nat., 5. ser., 19 (1910), II, No. 2, pp. 63, 63; abs. in Chem. Zentbl., 1910, II, No. 12, p. 313).—To a slightly acid boiling solution of the alkali salts of both of the above-named acids add from 10 to 15 cc. of a concentrated solution of ammonium nitrate and about 1 gm. of solid ammonium molybdate. After the ammonium molybdate is dissolved, boil for another 1½ minutes. The formation of a white precipitate indicates the presence of arsenic acid. Where much arsenic acid is present the precipitate is thrown down at once, but with smaller amounts boiling for a longer period is necessary.

Investigations on the estimation of inorganic phosphorus in animal tissues, A. C. Whittier (Jour. Indus. and Engin. Chem., 3 (1911), No. 4, pp. 248–250).—Considerable difficulty was experienced in this work in obtaining concordant results with the barium method (E. S. R., 17, p. 635), owing to the fact that the solution as obtained was, in most instances, cloudy. Where the solutions were clear, or the extracts were first coagulated, the results were fairly concordant with those obtained by the magnesium method (E. S. R., 23, p. 303). In most instances, however, the results for organic phosphorus were high. This difference in result the author does not believe is due to a hydrolysis of the organic into the inorganic state, but rather to the fact that a better precipitation takes place when the solutions are clear. Enzymes and the bacteria, according to the author, "seem to exert more of a hydrolyzing influence on organic phosphorus compounds of animal tissues than does boiling." The heating of flesh extracts has a tendency to check the activities of such organisms.
A study in the determination of calcium, G. Heise (Proc. Iowa Acad. Sci., 17 (1910), pp. 135-138).—This work had for its purpose the simplification of the gravimetric determination of calcium. The author points out that the precipitation of calcium as oxalate and its subsequent conversion into oxid by heating presents many difficulties and liability to inaccuracies to the inexperienced analyst. Tests were therefore conducted in order to determine if calcium could be estimated by weighing it directly as calcium oxalate.

The author concludes as follows: “Calcium can be determined and accurately weighed as the oxalate. It can be very conveniently converted into the carbonate and weighed as such. The determinations can be carried out in porcelain crucibles without appreciable error. Either of the above mentioned methods is fully as accurate as the determination of calcium as the oxid and is much more convenient and rapid. Of the 2 methods, the determination as carbonate is somewhat superior to the determination as oxalate, because of the hydroscopic nature of the latter substance.”

Methods of determining the dry-matter content of roots, R. K. Kristensen (Tidsskr. Landbr. Planteavl., 18 (1911), No. 1, pp. 96-108, figs. 5).—Comparative results obtained with a disc beet sampler and a Helweg “beet saw” showed that the latter gave the more satisfactory and correct results.

In order to ascertain the degree of accuracy that can be reached in determining the dry-matter content of roots, 60 samples of mangels were taken from the same lot of roots, triplicate determinations being made in all cases. The dry-matter content was found to vary between 13.67 and 15.59 per cent, with an average of 14.60 per cent. The largest deviation from this percentage was 0.90 per cent. The average analytical error was 0.36 per cent. As a rule, the error in an ordinary, well-conducted analysis will not exceed 0.3 per cent, and in most cases is below 0.2 per cent of dry matter.

Estimation of the doughing value of flour, A. A. Besson (Chem. Ztg., 35 (1911), No. 28, pp. 245, 256; abs. in Analyst, 36 (1911), No. 422, p. 216).—The author found that of the 2 methods proposed by Arragon, that by adding water to a definite amount of flour was the best. He endeavored to standardize the method and to eliminate the sources of error, if possible. It was found that a high result is obtained if all the water is added to the flour at one time, but that when added gradually the results were low.

The author, therefore, recommends adding at once 50 per cent of water to 150 or 200 gm. of the flour in a porcelain dish. The dough is then made as stiff as possible by working it with a glass rod. Strong kneading with the palm of the hand is absolutely necessary, and during the process the dough is squeezed between the fingers and pressed tightly against the palm. More water is then introduced during the process to obtain a uniformly wetted dough. The doughing is complete when it no longer sticks to the fingers, and the dough is then scraped together with the spatula and weighed.

These tests should agree within 1 per cent of added water, but allowance must be made for the moisture originally present in the flour, and the results reported in terms of dry substance.

A new method for the quantitative estimation of saccharose in the presence of other sugars, A. Jolles (Ztschr. Untersuch. Nahr. u. Genussmll., 20 (1910), No. 10, pp. 631-638).—This method has been previously described (E. S. R., 24, p. 704), and comments thereon noted (E. S. R., 25, p. 412).

Contribution to the examination of molasses, A. Jolles (Osterr. Ungar. Ztschr. Zuckerindust. u. Landw., 39 (1910), No. 5, pp. 698-703).—The author has modified a method previously noted (E. S. R., 24, p. 704) in order to apply it to the analysis of molasses. The results for sucrose, raffinose, and invert sugar obtained with the method were satisfactory.
In regard to apple marmalade and jelly, H. Pellet \( (\text{Monit. Sci.,} 4, \text{ser.,} \ 24 \ (1910), \ II. \ No. \ 828, \ pp. \ 777-784); \ abs. \ in \ \text{Ann. Falsif.,} 4 \ (1911), \ No. \ 29, \ p. \ 163) \).—The author criticizes the work of Chauvin (E. S. R., 23, p. 167) in regard to the use of Clerget's method for determining sucrose, levulose, glucose, and invert sugar (inverted by the acid present in the apple), and states that the conclusions drawn by this author are diametrically opposed to the results obtained by himself and others.

He concludes that dextrin is not attacked by a 10 per cent solution of hydrochloric acid and thus has no influence upon the results obtained with the Clerget test. Furthermore, a mixture consisting of 75 gm. of sugar and 5 gm. of dextrin in 100 cc. of water acidified with tartaric acid will give exact results for sugar, while dextrin is not affected when heated to 95° C. for 15 minutes or at 100° C. for 15 minutes, nor when heated while exposed to the atmosphere. Such a mixture shows a boiling point of 115° C. Prolonged heating of solutions of this composition with 10 per cent hydrochloric acid at from 80 to 82° C. for 3 hours showed a complete inversion of the dextrin. The plane of rotation of the invert sugar turned to the right, but the reducing power did not vary much from that in the solution in which tartaric acid was used.

Experiments with yeast yielded the same results.

Detection of fusel oil in brandy, E. Herzog \( (\text{Ztschr. Untersuch. Nahr. u. Genussmll.,} \ 21 \ (1911), \ No. \ 5, \ pp. \ 280-282) \).—The author points out that Holländer's reaction (E. S. R., 23, p. 216) is due to the co-presence of furfural and the fusel oil in brandy. He considers if a furfural reaction because no emerald-green coloration could be obtained with an alcoholic solution of fusel oil, Benzaldehyde, oil of fennel, and oil of cinnamon give a similar reaction with Holländer's reagent.

Determination of lactose in milk, Vitoux \( (\text{Ann. Falsif.,} \ 3 \ (1910), \ No. \ 25, \ pp. \ 471, \ 472) \).—The author points out that practically the same results can be obtained by the French official and Denigès methods. The latter method is preferred for milks preserved with potassium bichromate. Both methods are given in detail.

On the peroxidase of cows' milk and its detection by means of the paraphenylenediamin test, E. Nicolas \( (\text{Bul. Soc. Chim. France,} 4, \text{ser.,} \ 9 \ (1911), \ No. \ 6, \ pp. \ 266-269) \).—In this work it is pointed out that while precipitated and boiled casein will give a reaction (blue coloration) with paraphenylenediamin and hydrogen peroxid, it is the latter which first acts with the paraphenylenediamin, and that the casein only subsequently combines with it in order to give the blue coloration. The reaction, furthermore, takes place only when hydrogen peroxid and paraphenylenediamin are present in concentrated solutions. In dilute solutions the reaction appears only when a little bran is added.

The above findings are contrary to those obtained by Bordas and Touplain (E. S. R., 23, p. 417).

Refractometric milk examination, G. Kühn \( (\text{Ztschr. Untersuch. Nahr. u. Genussmll.,} \ 20 \ (1910), \ No. \ 9, \ pp. \ 575-579) \).—The author points out the accuracy with which water can be detected with the Ackermann method (E. S. R., 25, p. 207) using numerous samples of commercial milks and the corresponding barn samples. In practically all instances conviction was obtained on the basis of the refractometric test.

In regard to the origin of ammonia in milk, L. Marcas and C. Huyge \( (\text{Rev. Gén. Lait.,} \ 8 \ (1911), \ No. \ 21, \ pp. \ 481-486) \).—The authors, using Trillat and Sauton's test (E. S. R., 17, p. 287), examined commercial milks in different parts of France in order to determine the frequency of the occurrence of am-
monia in milk. From their work they conclude that the presence of ammonia in milk is always an indication that it has been kept under unhygienic conditions or has been watered. On the other hand, they show that the absence of ammonia in milk does not always indicate that the milk has not been watered or has been properly cared for.

Commercial tests for moisture in butter, C. W. Larson (Pennsylvania Sta. Rpt. 1910, pp. 147-155, pls. 5).—This is a study of the relative value of the several commercial moisture tests for butter thus far proposed (the Wagner-Gray, Irish, Wisconsin-high-pressure-oven, Ames-paraffin, and Marshall tests) as compared with the official gravimetric method.

"The results obtained from Wagner's moisture test are not always accurate. Very accurate results can be obtained with the Wisconsin high pressure oven, the Ames, and the Marshall tests, and if care is taken in the heating of the cup in the Irish test good results can be secured." . . .

Observations on some methods of estimating coconut oil and butter in butter and margarin, C. Revis and E. R. Bolton (Analyst, 36 (1911), No. 424, pp. 333-342, fig. 1).—The Polenske method according to these authors, who have applied it to numerous samples, is the only chemical method whereby small amounts of coconut oil can be detected and approximately estimated in butter, failures being due largely to a lack of scrupulous attention to the experimental details involved in the method.

The authors have, however, compared the effect of maintaining a constant temperature in the still-head with results obtained under the usual conditions of work. They conclude that "so long as reasonable care is taken to protect the still-head from draft, no error arises from this source; and as the maintenance of a high temperature depresses both the Reichert-Meissl and Polenske values, there is no advantage in employing a specially protected high-temperature still-head, beyond the fact that time, and to a certain extent the type of distillation, become of less importance."

The Shrewsbury and Knapp method (E. S. R., 21, p. 515), the cadmium method of Paul and Amberger (E. S. R., 21, p. 110), and Kirschner's method (E. S. R., 16, p. 1650) were also studied. The Shrewsbury and Knapp method was open to the objection that concordant results could not be obtained with the same samples. It was also modified by the authors, but the figures obtained with it were not as reliable as those obtained by the Polenske method. The cadmium method after a few tests was abandoned on account of its laborious execution and bad results in the authors' hands.

The Kirschner method was found to offer little in advance of the Polenske method for coconut oil and butter, but it had a decided advantage when applied to margarin containing both butter and coconut oil, or margarin containing coconut oil alone. It is the authors' conviction "that it is the only published method at present available which will decide whether butter fat is present in a margarin containing coconut oil, even if the amount be only 2 per cent in conjunction with 75 per cent or more of coconut oil." The method as employed by the authors is described in detail.

Examination of Shrewsbury and Knapp's process for the estimation of coconut oil, R. Ross, J. Race, and F. Maudsley (Analyst, 36 (1911), No. 422, pp. 195-198).—This investigation was conducted with Irish, Danish, Finnish, Siberian, German, and English butters, coconut oils from various sources, cacao butter, and coconut stearin.

The highest Shrewsbury and Knapp figure for the butter was found to be 35.5 in contrast to 32 as suggested by Shrewsbury and Knapp as the maximum.

The authors point out that "in considering the genuineness or otherwise of a butter, it is doubtless advisable not to rely entirely on any particular figure,
but to consider the case as a whole.” It was found absolutely necessary to follow the process exactly as described by the authors, particularly as regards glycerol saponification. The method is probably of use in determining the composition of margarin.

A method for the determination of butter fat in ice cream, J. W. White (Pennsylvania Sta. Rpt. 1910, pp. 243–247).—A method is proposed for using the Babcock test in the determination of butter fat in ice cream, as follows:

“Place the [Erlenmeyer] flask [containing the properly sampled ice cream] into a bath of water heated to 80° F. and shake frequently by giving the flask a gentle rotary motion until the contents assume the consistency of thin cream. Pour the melted cream through a cream sampling sieve into a beaker, rubbing through the fingers any lumps that may be left on the sieve; pour several times from one beaker to another until the sample is thoroughly mixed, and then weigh out into a whole milk bottle while the sample is still warm, 6 gm. by means of cream balances, and make the total volume up to 18 cc. Eight cc. of oil of vitriol (specific gravity 1.83) are now added in 2 portions of 4 cc. each, allowing about 2 minutes to elapse before the addition of the second portion and mixing carefully the contents of the bottle after the addition of each portion. The mixture at this stage should be of a light brown color and not black as is the case with milk. If a black color is obtained, it is best to reject the determination and weigh out a second portion, adding a smaller amount of acid, because the sample contains little casein as compared with milk, and the black color is due to the too violent action of the acid upon the sugar which it chars and makes a clear reading very difficult. The bottle is now placed in the steam tester and whirled for 3 minutes at the highest possible speed, [Soft or] distilled water (150° F.) sufficient to bring the fat up to the base of the neck is added. If any black particles are intermixed noticeably with the fat, shake the bottle vigorously for a few seconds. Whirl again for 3 minutes as stated above, and add sufficient water, drop by drop, to bring the fat column between the 10 per cent and the zero marks. Whirl the third time for 2 minutes, and take the reading at 145° F. The resultant fat column should be of a golden yellow color, free from any dark particles of charred sugar. Multiply the reading by 3, as the bottle is graduated on a basis of 18 gm.

“In reading the percentage of fat, the bottle should be held upright with the graduated scale of the neck of the bottle on a level with the eye.”

The methods used for sampling and weighing the ice cream under examination are also given.

A new method for the determination of fat and fatty acids in feces, O. Folin and A. H. Wentworth (Jour. Biol. Chem., 7 (1910), No. 6, pp. 421–426; abs. in Zentbl. Physiol., 24 (1910), No. 21, pp. 976, 977).—The method is as follows:

One gm. of the dried and finely divided feces is packed into a piece of fat-free filter paper, put in a thimble, placed in an extraction apparatus, and extracted with 150 cc. of water-free ether which has been previously saturated with hydrochloric-acid gas. The ethereal fat solution (extract), which is contained in a 250 cc. solution flask, is now distilled until nearly all of the ether is driven off; then 50 cc. of petroleum ether (boiling point not over 60° C.) is added, allowed to stand over night, filtered through cotton, the volatile portion evaporated off, and the residue dried at 95° C. for 5 hours and weighed as neutral fats and fatty acids. The residue is then dissolved in 50 cc. of benzol, from 1 to 2 drops of alcoholic phenolphthalein is added, the solution brought nearly to boiling, and immediately titrated with a volumetric solution of sodium alcoholate (2.3 gm. of sodium in a liter of absolute alcohol).
The results show that the majority of the fatty acids in feces exist as stearin. In these tests the total fat fluctuated between 13.5 and 20.2 per cent, and the neutral fat from 4.5 to 5.4 per cent.

A clinical method for the quantitative determination of uric acid in blood, P. Rothlisberger (München. Med. Wchnschr., 57 (1910), No. 7, pp. 344-357, figs. 4; abs. in Chem. Ztg., 31 (1910), No. 59, Repert., p. 229).—Uric acid quickly reduces freshly prepared silver carbonate. The author utilized this reaction and has perfected a method in which as little as 0.001 mg. can be detected in blood serum.

Methods for the examination of bituminous road materials, P. Hubbard and C. S. Relve (U. S. Dept. Agr., Office Pub. Roads Bul. 38, pp. 5, figs. 18).—This bulletin has for its purpose the presentation of the testing methods in use by the Office of Public Roads of this Department.

The topics treated include the classification of bituminous road materials, the scheme of examination, specific gravity and specific viscosity determinations, the float and penetration tests, melting point, flash and burning point determinations, volatilization and distillation tests, determination of bitumen soluble in carbon disulphid and insoluble in paraffin naphtha and in carbon tetrachlorid, determination of fixed carbon and paraffin scale, extraction of bituminous aggregates, grading the mineral aggregate, and determination of voids in the mineral aggregate. An appendix enumerates laboratory equipment, and presents metric conversion tables and similar data, and forms for reporting tests.

(Report of the department of chemistry), C. A. Jacobson (Nevada Sta. Bul. 731, pp. 47-59).—In studies of the relation of the nitrogen to the organic constituents in the alfalfa plant what appear to be 3 compounds have been isolated from the alcoholic extract. One resembles a phosphatid, containing nitrogen, oxygen, hydrogen, and carbon, another contains neither nitrogen nor phosphorus, but carbon, hydrogen, and oxygen, and the third is soluble in water and resembles a protein. The distillate obtained from the dry distillation of sagebrush by the Sparling process has been analyzed.

Filtration of cloudy vinegars through infusorial earth, H. Wüstenfeld (Deut. Essigindus., 15 (1911), No. 29, p. 230).—The author recommends infusorial earth (kieselguhr) as a filtering medium for cloudy vinegars.

METEOROLOGY—WATER.

The application of meteorological data in the study of physiological constants, H. L. Price (Virginia Sta. Rpts. 1909-10, pp. 206-212, figs. 2).—The purpose of this paper is "to call attention to the application of the law of van't Hoff and Arrhenius to the changes involved in blooming phenomena and to emphasize the need of recognizing this principle in the study of the problem of physiological constants. While an arbitrary 'critical' temperature of 32° or 43° F. and an arbitrary period of dormancy, as January 1, and a sum total of positive temperature readings above the critical temperature selected may lead to constants which are roughly approximate, yet this method is faulty and can not be the means of establishing true physiological constants."

Alaska's climate, C. C. Georgeson (Alaska Sta. Rpt. 1910, pp. 76-85).—This is a summary in the usual form of observations on temperature, precipi-
tation, and weather conditions at the different Weather Bureau stations in Alaska.

**Meteorology, H. D. Edmiston** (*Pennsylvania Sta. Rpt. 1910*, pp. 255-266, 607-630).—The observations here recorded are of the same character as those reported in previous years (E. S. R., 23, p. 516). The summary for 1909 is as follows:

**Summary of meteorological observations, 1909.**

**Meteorological notes, H. L. Price** (*Virginia Sta. Rpts., 1909-10*, pp. 224-232, *figs. 5*).—This is a summary of meteorological data secured since the publication of a 10-year summary in 1905 (E. S. R., 17, p. 836), and gives tabular records of temperature, precipitation, prevailing wind, sunshine, and charts showing the maximum, mean, and minimum temperatures by months and monthly precipitation. For the sake of comparison, the temperature and precipitation charts for 1893 to 1904 are reproduced. A general summary for the 15-year period is given.

The mean annual temperature for the 15 years was 51.34° F., the maximum 98°, the minimum -13°. During the period the temperature fell below zero on January 10, 11, 15, and 16, 1893; December 29, 1894; January 12 and 13 and February 3, 6, 7, 8, 9, and 15, 1895; February 20 and 21, 1896; January 23 and 30, 1897; February 3 and 4, 1898; February 1, 9, 10, 11, 13, and 14, and December 31, 1899; February 1, and March 17 and 18, 1900; December 16 and 21, 1901; February 19, 1903; January 30 and February 6, 1904; February 14, 1905; February 7, 1907; February 2, 1908; November 16, 1908; and January 31, 1909. The temperature rose above 95° on August 10 and 11, September 3 and 10, 1900; and July 17, 1902. The mean annual precipitation for the period was 40.86 in. The highest monthly precipitation, 12.29 in., was in July, 1905, the lowest, 0.13 in., in October, 1904. The greatest depth of snow in 24 hours, 11 in., occurred January 9, 1895. The average date of last killing frost in spring was April 26, of first killing frost in fall October 2. The latest killing frost recorded was May 22, 1907, the earliest, September 22, 1897.

**Meteorological, magnetic, and seismic observations of the College of Belen of the Society of Jesus, Habana. 1910, L. Gangoiti** (*Observatorio Meteorologico, Magnetico y Seismico del Colegio de Belen de la Compania de Jesus en la Habana, año de 1910. Habana, 1911*, pp. 95, *dgmns. 3*).—Detailed reports, largely tabular and diagrammatic, of the usual observations.

**Sixth annual report of the meteorological committee** (*Ann. Rpt. Met. Com. [Gt. Brit.], 6* (1911), pp. 164, pls. 9, *figs. 3*).—This consists as usual of adminis-
trative reports regarding organization and operations (during the year ended March 31, 1911) in marine meteorology, forecasts and storm warnings, climatology, publications, investigation of the upper air, and miscellaneous subjects, with appendices as follows: Financial statement, supply of information to the public, lists of observers who sent in "excellent" meteorological logs during the year and of logs and documents received from ships, distribution of instruments, report on inspection of meteorological stations, and lists of persons and institutions from whom publications and meteorological data have been received and to whom publications are sent.

Variations in the English climate during the thirty years 1881–1910, W. Marriott (Quart. Jour. Roy. Met. Soc. [London], 37 (1911), No. 159, pp. 221–232, figs. 8; rev. in Surveyor, 40 (1911), No. 1027, pp. 359–361).—This article contains a set of tables based upon means of temperature, pressure, rainfall, and wind for the British Isles, and gives data bearing upon variations in mean monthly temperatures, recurring warm and cold months in successive years, hot and warm spells, recurring wet and dry months in successive years, and dry and wet spells.

British rainfall, 1910, H. R. Mill. (London, 1911, pp. 112±328, pls. 6, figs. 67).—This report deals as usual with the amount and distribution of rainfall in the British Isles during 1910, as recorded by nearly 5,000 voluntary observers belonging to the British Rainfall Organization.

It contains a report of the director giving a detailed account of the year's work, and special articles on the greatest rainfall which may occur on the wettest day of the year, the rearrangement of the rainfall stations, and the rain gage in theory and practice. There are also records of evaporation and percolation at Camden Square, London, and several other places.

A new feature of this report to which special attention is called is the rearrangement of the stations in river basins, the county being retained as the unit. The cartographic treatment of rainfall data has also been carried further than in previous volumes and a new rainfall average has been introduced.

The average rainfall for the British Isles in 1910 was 41.77 in. as compared with a ten year average, 1900 to 1909, of 38.39 in., and a thirty-five year average, 1875 to 1909, of 38.49 in. The mean evaporation at 11 stations was 16.37 in. The percolation at 3 stations from which records were secured varied from 50 to 62 per cent of the rainfall.

On the absorption of ammonia from the atmosphere, A. D. Hall and N. H. J. Miller (Jour. Agr. Sci., 1 (1911), No. 1, pp. 56–68; abs. in Jour. Chem. Soc. [London], 100 (1911), No. 586, II, pp. 763, 764).—Monthly determinations during two years of the amounts of atmospheric ammonia absorbed by dilute sulphuric acid in dishes 26.5 cm. in diameter are reported.

"The highest results were obtained with dishes kept at a height of about 115 cm. above the ground in front of the Rothamsted laboratory, near the outside of the town, the nitrogen absorbed amounting to 1.48 lbs. per acre per annum. In dishes in the same situation, but only 5 cm. above the ground, the amount absorbed was only 0.85 lb.

"Dishes placed in the experimental grass plots showed somewhat higher results in the upper dish (0.78 lb.) than in the lower one (0.70 lb.). In the experimental wheat field the absorption in the upper dishes was 1.14 lbs., and in the lower dishes 1.53 lbs. The higher results obtained in the wheat field as compared with the grass plots are mainly due to considerable amounts of
ammonia given off by the soil for some weeks following the application of ammonium salts to some of the wheat plats. In April, 1909, the absorption in the upper and lower dishes in the wheat field was 0.29 and 0.61 lb., respectively. During the ten months not affected by the manures, the average absorption in the wheat field was higher in the upper than in the lower dishes."

Impurities in the atmosphere of towns and their effects upon vegetation, A. G. Ruston and C. Crowther (Epl. Brit. Assoc. Adv. Sci., 1910, pp. 577, 578).—A study of the impurities in samples of air, taken in different parts of the city of Leeds and at a point in the country 7½ miles distant from the center of the city, showed a relatively high content of suspended matter and acid in the town air, both of which are carried down in the rain in sufficient quantity to be distinctly injurious to vegetation.

Some stream waters of the western United States, with chapters on sediment carried by the Rio Grande and the industrial application of water analyses, H. Stabler (U. S. Geol. Survey, Water-Supply Paper No. 274, pp. 188).—This is "a report setting forth the results of a systematic study of the waters likely to be utilized on the Reclamation Service projects. This study was made in order to determine the influence of the saltness of the waters on the growth of vegetation and the effect of suspended matter in silting canals and reservoirs. [The report] contains tables giving analyses, gage heights, rates of discharge, and relative amounts of substances in solution in the waters of different rivers."

Geology and water resources of Estancia Valley and adjacent parts of central New Mexico, O. E. Meinzer (U. S. Geol. Survey, Water-Supply Paper No. 275, pp. 89, pls. 14, figs. 7).—This paper gives the results of brief reconnaissance surveys of Estancia Valley, an area of about 2,000 square miles near the geographic center of New Mexico, and of Encino basin, which lies immediately east of Estancia basin. Notes are given not only on geology and water resources, but also on soils and irrigation.

Chemical and biological survey of the waters of Illinois, 1909 and 1910, E. Bartow (Univ. Ill. Bul., 8 (1911), No. 23, pp. 128, figs. 28).—This contains a brief general report, notes on the organization of the Lake Michigan Water Commission and the Illinois Water Supply Association, and the following special articles: Composition and treatment of Lake Michigan water, the action of bleaching powder in water purification, treatment of water with boiler compounds, relation of typhoid fever and the water supplies in Illinois, analytical control of water softening, nitrite destruction test for a polluted water, a convenient camera for color comparisons in Nessler tubes, additional farm water supplies, a water works laboratory, and suggested disposal of drainage at Tolono.

The geochemical interpretation of water analyses, C. Palmer (U. S. Geol. Survey Bul. 479, pp. 31, fig. 1).—This bulletin is devoted to "an exposition of the principle that natural water may be definitely characterized if the salts dissolved in it are recognized not as a load but as a chemical system of balanced values. The relation of silica to primary alkalinity and the persistence of silica in river waters are among the topics considered."

The treatment of drinking water with ultraviolet rays, L. Schwarz and Aumann (Ztschr. Hyg. u. Infektionskrank., 69 (1911), No. 1, pp. 1-16, fig. 1; 68-91, figs. 3).—The results of numerous experiments are reported, showing that ultraviolet rays are effective in reducing the germ content of water but that the efficiency of the process depends upon the original germ content of the water and the thoroughness with which it is stirred during the treatment, as well as upon the length of treatment. Special care must be exercised in the
treatment of water containing large numbers of germs, and the authors are of the opinion that this method of treatment as at present developed is not practically applicable except under special conditions.

SOILS—FERTILIZERS.

The fixation of nitrogen in some Colorado soils, W. P. Headden (Colorado Sta. Bul. 178, pp. 3–96, pls 6).—Further investigations on the injurious nitrates in Colorado orchard soils (E. S. R., 23, p. 523) are reported, including additional analyses of the water-soluble portion of a number of soils from barren spots and tests of the rate of nitrogen fixation and nitrification in the soils.

The author states that the spread of the trouble during 1910 was very marked and that the intensity of the attacks has increased rather than abated. Areas of several hundred acres on which fruit trees are dead or dying as a result of nitrate injury are involved. "In one 14-year-old orchard not less than 12 acres of trees, apple, plum, pear, and cherry, together with currant bushes and other small fruit, have been killed in less than a year. The water table in this land was not, at any time, near enough to the surface to do any damage.

"No single instance of the death or eradication of a brown area, a niter spot, has been observed; but the interior of such areas has been found so excessively rich in salts that the ground has become barren, even of the Azotobacter flora.

"This department of the bacteria suggests the probability that the land may again become fertile after a few years, in fact. varieties of Atriplex, salt-bushes, are already taking possession of land which has been devoid of vegetation for several years.

"The drainage in several of the cases given is excellent, in other cases drains have been laid for periods of from one to five years without preventing the formation of niter areas.

"Trees badly affected by this trouble show almost no recuperative power, probably due to the continued excessive supply of nitrates in the soil, possibly to the severe toxic action of the nitrates. So far as our observation goes both factors seem to be involved. Slightly affected trees may recover but no badly affected tree has been observed to do so.

"The generally observed change in the soil, indicating danger to the trees, is a turning brown of the surface which is expressed by the statement that 'the soil turned brown or black and the trees died.'

"The samples of brown soil have, without exception, contained excessive quantities of nitrates.

"The color is not due to the nitrates nor to sodic carbonate or black alkali proper but to the development of pigments by the Azotobacter. This applies to the soils here described. Some soils may have a brown color due to other causes.

"This condition is usually preceded and accompanied by a mealiness of the soil, often described as ashy. There is usually but little or no efflorescence on such soils though it sometimes occurs.

"The time required for the killing of a tree varies with the virulence of the attack, in bad cases from four days to two weeks. Slightly affected trees may linger a long time.

"These areas may occur in perfectly drained land, situated in the midst of land which shows no abnormal quantities of nitrates.
"In one case, and possibly in others also, injury to many trees followed the application of water, probably due to the washing of the nitrates down into the soil . . .

"The ordinary white alkali that commonly occurs in these sections is, for the most part, free from nitrates, but the brown and white areas frequently overlap.

"The ground waters, unless derived from niter areas, are free from nitrates and these nitrates cannot be accounted for by the evaporation of such water from the surface of these areas.

"In some sections practically the whole of the irrigated land has been affected, thus eliminating the question of transportation except as to the river water used for irrigation. Our river waters carry from 0.00 to 0.4 part per million of nitrogen as nitrates.

"The localization of these areas and the rate of increase also preclude the theory of transportation and concentration.

"Excessive irrigation for the purpose of washing out the‘black alkali,' nitrates, has not been successful, but this failure has probably been due to the method used.

"The liberal application of manure has not given permanent, if indeed, any relief.

"Thorough and frequent cultivation has not been followed by the beneficial results expected.

"The soils of Colorado are, generally speaking, poor in nitrogen, but the ratio of nitric nitrogen to the total nitrogen is frequently very high, 17 to 50 per cent being not uncommon.

"The nitrogen in these soils is fixed by Azotobacter which use the nitrogen in the air to build up their tissues.

"The fixation of nitrogen, in a sample of ordinary soil from the college farm, collected December 12, 1910, on incubation for 27 days was found to have taken place at the rate of 5.222 lbs. of nitrogen, equal to 17.5 tons of proteids per acre-foot of soil per annum.

"The nitric nitrogen present in this soil at the beginning of the experiment corresponded to 840 lbs. of sodic nitrate per acre-foot of soil; this had increased in 48 days to 1,999 lbs. as a maximum, a gain of 1,159 lbs. which would give, if this rate were continued for a year of 360 days, a gain of 8,676 lbs., or 4.1 tons of nitrates per acre-foot of soil.

"The incubated samples, with but one exception, showed a darkening of their surfaces.

"No addition of anything except boiled, distilled water was made to these samples before or during incubation. A large bottle was partially filled with some, approximately 8 lbs., of the original sample just as it was collected. This bottle was loosely stoppered, inverted and kept in a room where the temperature was fairly high and even. This soil was analyzed just as the incubated samples were and showed a decided increase in both the total and nitric nitrogen, 7.45 and 19.15 per cent respectively.

"Fixation takes place rapidly in this soil in the presence of from 13.5 to 20 per cent of water. The rate of fixation of nitrogen obtained is sufficient to account for the nitrates found in the soil provided that it is nitrified.

"The rate of nitrification obtained is sufficient to account for the formation of the nitrates found, in most cases if not all of them.”

Bacteriological studies of the fixation of nitrogen in certain Colorado soils, W. G. SACKETT (Colorado Sta. Bul. 179, pp. 3-42, pls. 2, figs. 5).—With a view to determine the source of the excessive amounts of nitrates in certain Colo-
rado soils (E. S. R., 23, p. 221) the author made a bacteriological study of the nitrogen fixing power of these soils in nutrient solutions and in the soils themselves. A study was also made of the relation of nitrates, other nitrogen compounds, and various salts in the nutrient solution to the characteristic brown color of the niter spots. In most of the culture work the mannite solution recommended by Lipman was used except that tripotassium phosphate (K₃PO₄) was substituted for the dipotassium phosphate (K₂HPO₄).

The author concludes from the results obtained in these studies that "the power to fix atmospheric nitrogen is a property common to many cultivated Colorado soils. This power is not confined to nitrogen fixation in solutions, but is manifested in soils as well. 'The rate of fixation of nitrogen obtained is sufficient to account for the nitrates found in the soil provided that it is nitrified. The rate of nitrification obtained is sufficient to account for the formation of the nitrates found, in most cases if not all of them.' "

"The nitrogen fixing power is not limited to any geographical locality or class of soils, however the adobe shale soils, both in a raw state and newly cultivated, possess little if any nitrogen fixing power. Excessive nitrates either destroy or greatly attenuate the nitrogen fixing flora of a soil. A limited amount of soil nitrate does not seriously affect the nitrogen fixing power of a soil; Azotobacter chroococcum appears to be the dominant nitrogen fixing organism in the soils studied. The dark brown color of the niter soils is due, in a large part, to the pigment produced by A. chroococcum. Given a source of energy, the nitrate is the limiting factor in the production of the brown color. In the presence of nitrates, A. chroococcum develops a chocolate brown to black pigment; nitrites, in certain amounts, produce similar results, but to a less degree; nitrogen as NH₄Cl., (NH₄)₂SO₄, asparagin, and peptone has no effect upon this function. The highly colored extracts obtained from certain niter soils suggest that the pigment of A. chroococcum may be soluble in the alkaline soil waters. Excessive soil moisture, by interfering with the growth of A. chroococcum prevents the formation of the brown color on the soil, and makes the fixation of atmospheric nitrogen impossible."

The fixation of nitrogen by means of Bacillus radicicola without the presence of a legume, E. B. Fred (Virginia Sta. Rpts. 1909-10, pp. 138-142, figs. 3).—The results of experiments in liquid media, sand, and soil show that the nitrogen assimilation, although very small, "was sufficient to give a reasonable basis for the belief that B. radicicola will live in the soil without the host plant and accomplish a certain amount of nitrogen assimilation."

A comparative study of the bacterial content of soils from fields of corn and alfalfa, H. H. Waite and D. H. Squires (Nebraska Sta. Rpt. 1910, pp. 160-177, figs. 4).—This article reports counts and studies of cultural characteristics of the bacteria to a depth of 12 ft. in two fields of loess soil which have been in cultivation for 30 years. The cornfield had never been cropped in alfalfa; the alfalfa field had been in alfalfa for the past seven years.

Corn soil showed a decidedly greater number of bacteria in the first 3 ft. than the alfalfa soil. "Azotobacteria were shown to be in all levels of the alfalfa field except the first, seventh, tenth, and eleventh; and in all levels of the cornfield except the first, third, fourth, and eighth foot, showing a good distribution of Azotobacteria as to depth."

The great majority of the organisms isolated were acid formers. The methods used are described and a bibliography of 32 references is given.
Some observations on humus formations in the soil, S. P. KRAKOV (Dneew. XII. Stézda Russ. Est-*isp. i Vrach. [Moscow], p. 638; abs. in Zhur. Opyn. Agron. (Russ. Jour. Exp1. Landw.), 11 (1910), No. 5, p. 736).—An examination of the composition of the ash of different plant residues and of the black extract of the underlying soil horizon showed a relationship which may be used in classifying the humus formations.

A contribution to the knowledge of the protozoa of the soil, T. GOODEY (Proc. Roy. Soc. [London], Ser. B, 83 (1911), No. B 570, pp. 165-180, pl. I, fig. 1).—Investigating further the suggestion of Russell and Hutchinson (E. S. R., 24, p. 621) that protozoa limit the action of bacteria in soils with an accompanying decrease in ammonia production, the author found that “the ciliated protozoa which are so characteristic a feature of cultures made from soil only exist in the soil in an encysted condition. In consequence, they cannot function as the factor limiting bacterial activity in the soil.” The investigations dealt only with ciliated protozoa, not with amoebae and flagellates.

Earthworms and soil fertility, STEGLITZ (Fühling’s Landw. Ztg., 69 (1911), No. 15, pp. 538-542).—The author reviews the work of other investigators on the subject, with particular reference to the investigations by Russell (E. S. R., 24, p. 424), and takes the position that earthworms and other animal life have an effect not only in bettering the physical condition of the soil and thus promoting the production of nitrates, but that they render available as plant food the mineral elements of the soil as well.

The soil and the plant, E. J. RUSSELL (Sci. Prog. Twentieth Cent., v (1911), No. 21, pp. 135-152, pl. 1).—This is a review of American hypotheses of soil fertility, particularly those of the Bureau of Soils, pointing out the outstanding differences between them and those generally accepted. It is held that the results of experiments at Rothamsted point to the great importance of the nutritive function of the soil constituents and of added fertilizers, and the theory that plants excrete toxic substances is not accepted.

A bibliography of the literature is given.

Field operations of the Bureau of Soils, 1908 (tenth report), M. WHITNEY ET AL. (U. S. Dept. Agr., Field Operations of the Bureau of Soils, 1908, pp. 1428, pl. 8, figs. 38, maps 37).—This report contains a general review of the field operations of the Bureau of Soils during 1908, by the Chief of the Bureau, together with detailed accounts of the following surveys:

During the calendar year 1908, 22,250 square miles, or 14,259,200 acres, were surveyed and mapped in detail on a scale of 1 in. to the mile, making the total area surveyed and mapped up to the end of that year 171,757 square miles, or 169,943,080 acres. The average cost of the field work in 1908 was $3.33 per square mile.

In addition to the detailed surveys, there were conducted in 1908 reconnaissance surveys in parts of North Dakota, Pennsylvania, and Texas, covering a total area of 50,352 square miles, or 32,225,280 acres. The average cost of these surveys was 32 cts. per square mile.

These reconnaissance soil surveys were undertaken in 1908 in the region west of the one hundredth meridian, work being started both in North Dakota and Texas to determine the character of the soil and crop adaptations in the Great Plains region. Similar work has also been begun in the cut-over timber lands of the Great Lakes section, and arrangements have been made for the study of the cut-over timber lands of the Puget Sound region in conjunction with the State of Washington.

A report on the agriculture and soils of Kent, Surrey, and Sussex, A. D. Hall and E. J. Russell (London: Bd. Agr. and Fisheries, 1911, pp. VIII + 206, pls. 42, figs. 4).—Since the publication of a preliminary report on the soils of Kent and Surrey counties (E. S. R., 14, p. 644) the scope of this survey has been so enlarged as to add Sussex County to the area and to include the general agriculture of the region. The mechanical analyses of the soils previously made at Wye have also been repeated in order to obtain uniformity in the results here reported, there being variations in the method of analysis now followed (sieve and sedimentation) and that adopted in the earlier work. This book, therefore, is a complete and detailed report of a survey of the soils and agriculture of the counties of Kent, Surrey, and Sussex of southeastern England, and contains chapters on the natural features of the district, its agriculture, soils, including mechanical and chemical analyses, the relation of soils to crops, and building stones and other economic products.

The authors have taken the geological formations as the basis of their work, and their experience in the field “goes to show that each formation in the area under consideration gives rise to a distinct soil type, the characteristic composition of which can further be recognized by making up an average from the mechanical analyses of the samples taken from that formation.” The evidence also goes to show that the mechanical analysis “does determine the fundamental structure of the soils, and that fair agreement may be expected between the composition of samples taken in a particular area.”
It is hoped that the report "may demonstrate the possibility of a soil survey useful to the farmer, and indicate the lines on which it can be fruitfully carried out."

Relation between granitic and gneiss soils (Rez. Sci. [Paris], 49 (1911), I, No. 23, p. 723).—This article is based on the work of M. Sauer and points out the principal differences in the physical properties of granitic and gneiss soils.

Granitic soils are sandy and nonretentive of lime, gneiss soils are clayey and retentive of lime. In granitic soils the fine particles wash down into the subsoil where they form ferruginous organic cement (hardpan) which prevents the percolation of water. This phenomenon does not occur in gneiss soils. Granitic regions are apt to contain peat moors, whereas these are more rare in case of gneiss soils.

Mechanical analysis and cartographic grouping of rocks and soils, G. Tumin (Dvuen. XII. St"ezda Russ. Est.-Isp. i Vrach. [Moscow], p. 428; abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 11 (1910), No. 5, p. 732).—The author contends that the grouping of soils according to the proportion of clay and sand present is unsatisfactory and that a third constituent, silt, must be considered. The three-constituent formula more closely represents the peculiarities of the mechanical composition. The advantage of taking account of the three constituents is illustrated by results of examinations of a number of samples of soil.

Morphological types of soil formations, G. M. Tumin (Dvuen. XII. St"ezda Russ. Est.-Isp. i Vrach. [Moscow], p. 428; abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 11 (1910), No. 5, p. 732).—From the morphological standpoint soils are considered to be a body of definite organization and structure and on this basis the author outlines a classification of the soils of Russia.

Classification of clays, H. Streunne (Chem. Ztg., 35 (1911), No. 12, pp. 529-531).—The author reviews the present literature of the subject, stating that clay is formed from such kaolinized rocks as contain the principal clay minerals, namely, weathered feldspars and allophanes. Feldspars are crystalline and contain alumina and silicic acid in chemical combination; the molecular ratio of the two may vary between that of feldspar and kaolin. Allophanes are colloidal and contain aluminum and silicic acid gels. The molecular relation of the two varies between pure alumina and pure silicic acid.

Turkestan loess, S. S. Neustreyev (Dvuen. XII. St"ezda Russ. Est.-Isp. i Vrach. [Moscow], p. 193; abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 11 (1910), No. 4, p. 582).—The observations of the author led him to the opinion that views as to the eolian origin of the loess soils require a revision. In many places he detected a connection between the loess and the eluvial rocks of the Turkestan mountains, where the ancient species give fine-grained, carbonate-carrying, yellow products of weathering which are transported by the atmospheric agents to the slopes.

Examinations of soil samples, V. Lommer and A. Pauly (Ber. Land u. Forste. Deutsch-Ostafrika, 3 (1911), No. 5, pp. 248-262).—The authors report the results of chemical analyses of a number of samples of soil from British and German East Africa surrounding Lake Victoria Nyanza and extending south into British Central Africa, besides samples of the German cotton soils of the neighboring districts. The results show a high plant food content for the volcanic soils, a low phosphoric acid and in some cases a low potash content in the nonvolcanic soils, and a general moderately high nitrogen content in both soils.

Inferior soils in the Grafton-Casino district, H. C. L. Anderson (Agr. Gaz. N. S. Wales, 22 (1911), No. 3, pp. 185, 186).—The soils between Casino and
Grafton, New South Wales, being held in low esteem by settlers, the author analyzed 2 samples of these soils with a view to determine their adaptability to the growing of forage crops by judicious manuring and crop rotation, including legumes.

He came to the conclusion that the agricultural possibilities of these soils are better than those of others held in much higher esteem. The poorest sample contained fair amounts of nitrogen, potash, and phosphoric acid, 0.056, 0.051, and 0.063 per cent respectively, but the lime content was deficient, being only 0.076 per cent. The second sample was darker in color and deeper and contained nitrogen 0.077 per cent, potash 0.05 per cent, phosphoric acid 0.088 per cent, and lime 0.145 per cent.

Soil studies in 1909, B. E. Brown, W. H. MacIntire, et al. (Pennsylvania Sta. Rpt. 1910, pp. 47-129, pls. 3, dgm. 1, charts 1†).—The general plan and scope of these studies which were made on plats of the long-time rotation and fertilizer experiments of the station are described and reports are given on specific lines of investigation as follows:

Seasonal nitrification and soil moisture in four plats treated with commercial fertilizers (pp. 50-57).—Weekly determinations of moisture and nitrates in plats treated with sodium nitrate and ammonium sulphate indicated that the decreased yield of corn on the plats which had received ammonium sulphate continuously for a number of years was not due to a reduction of nitrates in the soil of the plats since a larger amount of nitrates was found in these plats than in those treated continuously with sodium nitrate. It was shown, however, that the lime requirements of the ammonium sulphate plats were greater than those of the sodium nitrate plats. There was no marked variation in the moisture content of the plats.

Seasonal nitrification, soil moisture, and lime requirement in four plats receiving sulphate of ammonia (pp. 57-63).—Studies similar to those noted above were made on plats of corn, oats, wheat, and hay which had been continuously fertilized with ammonium sulphate to determine the relation of the kind of crop as well as the fertilizing, to the soil conditions.

It was found that the lime requirement was greatest in the oat plat and least in case of the corn plat but that the lime requirement varied at different periods of growth. "The amount of nitrates recoverable from the 4 plats was greatest under corn; oats, wheat, and hay following in the order named. The effect of plowing, incorporation of organic matter and plant residues, etc., apparently were closely associated with the amount of nitrates formed. The amounts of moisture present at the time the different crop plants were growing showed no marked variation." It was found in pot experiments that the soil showing the smallest lime requirement (which also contained the greatest amount of nitrates) produced the greatest growth of wheat for a period of 18 days.

The relation of certain soil constituents under growing corn, oats, wheat, and grass as determined periodically (pp. 64-82).—In laboratory investigations on soil from certain plats of the long-time rotation experiments to determine the seasonal variations of water-soluble nitrogen, potash, lime, phosphorus, and total solids as influenced by growing plants, fertilizer treatment, soil temperature and moisture, rainfall, and tillage methods, the largest amounts of nitrates, water-soluble calcium and potassium, and moisture were found in the corn plat. The nitrates recoverable from the corn plat were greatly reduced as the season progressed, but the nitrate content of the grass and wheat plats was low throughout the season. The concentration of the soil extracts with respect to calcium and potassium was lowered as the season advanced. The water-soluble
phosphoric acid was largest in the corn plat, followed in order by oats, grass, and wheat. The soil extracts varied widely in concentration at different periods. Experiments in wire-gauze pots showed that in general the soils from which the greatest amount of water-soluble constituents was recoverable produced the best growth of wheat. Bottle culture experiments showed that the untreated extract of the soil of the corn plat produced better growth of wheat than the extracts of soils of other plats whether treated or untreated. The corn plat extract was benefited least by treatment with absorbent substances like carbon black. Boiling was especially effective in improving the extracts for the growth of wheat.

An investigation of the causes of variation in soil fertility as affected by long continued use of different fertilizers (pp. 82-91).—In studies similar to those noted above determinations were made of water-soluble nitrogen, calcium, potassium, phosphorus, and total solids, under corn in 8 plats receiving different treatment to ascertain the causes of the differences in yield on these plats.

Very little difference was found in the moisture content of the plats. The amount of nitrates recoverable varied considerably at different times during the growing period of corn and as a rule the greatest amount of nitrates was found in the high yielding plats early in the season. There were only slight variations in water-soluble calcium, but a marked variation in the water-soluble potassium, a close relation apparently existing between the field treatment and the amount of water-soluble potassium. The higher content, however, was not always associated with high yields. In general the amount of potassium recoverable decreased as the season advanced. There were only slight variations in the water-soluble phosphorus of the different plats. Determinations of total solids indicated that the least productive plats furnished extracts of greater concentration than the plats which produced the greatest yields.

Comparative physical and chemical studies of five plats, treated differently for twenty-eight years (pp. 92-117).—The chemical and physical studies here reported were made on plats of the long-time rotation experiments which had received lime, lime and manure, and commercial fertilizers continuously for 28 years.

The results were not conclusive as to the causes of differences in yield on the differently treated plats. Alcohol digestion or extraction seemed to offer promising means of determining the presence of crystalline organic bodies in soils and the character of the organic matter of the soil appeared to be an important factor in determining the differences in yield.

The forms of organic nitrogen in soils (118-129).—Previous work by other investigators on this subject is reviewed, and studies of the organic nitrogenous compounds in soils of certain of the long-time rotation plats by the method of Hausmann modified by Osborne and Harris (E. S. R., 15, p. 221) are reported.

The results indicate that the nitrogenous matter of limed soils is more resistant to agencies of decomposition than that of unlimed soils. The decomposition of the nitrogenous matter of limed soils apparently proceeds very gradually, resulting eventually in from 16 to 21 per cent of the nitrogen being given off as ammonia and from 21 to 34 per cent being converted into amino acids, the remaining 40 to 60 per cent of the nitrogen being either partially or almost wholly unavailable for plant use.

Studies in organic soil nitrogen, E. C. Lathrop and B. E. Brown (Jour. Indus. and Engin. Chem., 3 (1911), No. 9, pp. 657-660).—This is a brief account of studies noted above.

General composition of the grass lands contiguous to the general fertilizer plats, W. Frear and J. W. White (Pennsylvania Sta. Rpt. 1910, pp. 163-235, pl. 1).—Continuing previous work (E. S. R., 23, p. 521), an account
is here given of a detailed study of samples of soil from the roadways surrounding and running through the long-time rotation plats at the station for the purpose of determining if possible the differences between the character of soil of these roadways and of the differently treated plats, of which studies were not made at the time the rotation experiments were undertaken. The studies reported included "(1) an examination to determine the average mechanical composition of the soil—i.e., the proportions in which particles of different, specific dimensions, enter to make the entire soil, surface and subsoil; (2) a chemical examination, more complete than usual, into the composition of the mineral matters of the soil; (3) a general study of the soil's organic materials."

Among the more important facts brought out by these studies are that although formed by the weathering of limestone rocks the soil contained little if any calcium carbonate, while magnesia although less abundant than lime in the original rock was present in the soil in considerably larger amounts than lime. Quartz formed a large fraction of the undecomposed portion of the rock remains in the soil. The remainder of the undecomposed rock was chiefly an aluminum-potassium silicate with smaller quantities of soda, lime, magnesia, and iron. Manganese was present in small quantity and titanium was quite abundant. The surface soil was distinctly acid. The "active humus" content was 1.96 per cent in the surface soil and 1.08 in the subsoil. Pentosans were present in the organic matter to the amount of 0.142 per cent, forming 4.65 and 4.47 per cent, respectively, of the active humus of the surface and subsoil. The surface and subsoil, free from hygroscopic moisture, contained 0.1492 and 0.0676 per cent of nitrogen, respectively. The nitrogen content of the organic matter of the surface and subsoil was 4.18 and 3.98 per cent, respectively. The surface soil contained only 0.976 per cent carbon dioxide, the subsoil 0.143 per cent. There was 0.5 per cent of lime in the surface soil and a little less in the subsoil. The surface soil contained 0.7 per cent and the subsoil 0.9 per cent of magnesia. The soil contained 3.5 per cent of potash, three-fourths of which was in the undecomposed rock residues. The available potash by the Dyer method was 0.0111 per cent in the surface soil and 0.00817 per cent in the subsoil. Phosphoric acid was present to the amount of 0.13 and 0.1 per cent, respectively, in the surface and subsoil. The available phosphoric acid by the Dyer method was 0.008 per cent in the surface soil and 0.002 per cent in the subsoil. In spite of the fact that this soil appears to be fairly well supplied with phosphoric acid, it has always shown a marked advantage from the application of phosphates. This is ascribed to the presence of iron and alumina in large amounts and in conditions favorable to the formation of rather insoluble phosphates. Of the iron present in the surface soil about one-third was found to be in the ferrous condition, a smaller proportion of the ferrous iron being found in the subsoil.

The methods used in the soil study are described.

Contribution to the study of phosphoric acid in soils and fertilizers, W. B. Ellett and H. H. Hill (Virginia Sta. Rpts. 1909-1910, pp. 44-65, figs. 8).—This is a preliminary report upon laboratory and pot experiments which have been going on for several years to determine what becomes of the phosphoric acid from fertilizers left in the soil after the removal of the first crop, and to what extent this residual phosphoric acid becomes unavailable. The experiments were made with various typical Virginia soils and the phosphates used were phosphatic slag, and tricalcium, dicalcium, and monocalcium phosphates.

The experiments with various solvents used to determine the availability of the phosphoric acid showed "that the substances found in the different soil types fix phosphoric acid from water solutions into compounds of different solubility. The hydroxids of iron and aluminum lock up or fix 60 to 70 per
cent of the water-soluble phosphates into insoluble or, as measured by these
solvents, into unavailable form. Where lime was mixed with equal quantities
of iron or aluminum hydroxids, the fixation of phosphoric acid was not so
great, as 57 per cent was available, showing that a part combined with lime.
Where calcium and magnesium carbonates were used as a fixing agent the
resulting compounds were completely dissolved and would have to be classed
as available."

The weights of the crop produced in the pot experiments indicated "that
iron and aluminum do not fix the phosphoric acid in forms unavailable to the
wheat plant. As a part of the phosphoric acid was available in the iron and
aluminum compounds, as shown by the solvents, and as 0.6 gm. of phosphoric
acid was added to each pot, which would be more than could be removed by
the wheat, a second crop was grown, using oats, without the addition of more
phosphates. . . . The second crop of oats shows practically the same results
as the first crop of wheat, that is, the iron and aluminum compounds produce
more plant growth than the calcium compounds, and are more available. . . .
The corn experiments from the first and second crops confirmed the results
obtained with wheat and oats and indicate that the solvents used by chemists
to determine the availability of phosphoric acid, when applied to the products
of fixation or reversion of phosphates by iron and aluminum, do not represent,
in any way, their true availability, and can not be correlated with what the
plant can or can not assimilate."

The conditions of soil climate in relation to the nitrogen and soluble
phosphoric acid of the soil, R. Perotti (Read. Soc. Chim. Ital., 2. ser., 2
(1910), pp. 143–148).—The relation of climatic conditions in the soil to the
decomposition of organic matter and the formation of humus, and its influence
upon the nitrogen supply, bacterial activity, and availability of mineral con-
stituents of the soil, are briefly discussed in this article.

The influence of lime and humus on the mechanical and physical proper-
ties of clay, loam, and sandy soils, W. Thaeer (Gekrönt. Preisschr. Univ.
Göttingen, 1910, pp. 145; Jour. Landw., 59 (1911), Nos. 1, pp. 9–57; 2, pp. 107–
135; abs. in Jour. Chem. Soc. [London], 100 (1911), No. 585. II, pp. 648, 649;
Ztschr. Angew. Chem., 24 (1911), No. 37, p. 1776).—In investigations here re-
ported it was found that the calcium of soils was in combination with carbon
dioxide and colloidal acids and in case of humus sand also in combination with
strong mineral acids. The addition of lime to the soils resulted in a precipita-
tion of colloids, in an increase of permeability and water-holding power, and in a
decrease in shrinkage on drying.

As regards permeability, the action of lime on the humus colloids and the clay
colloids was the same, but it decreased swelling of the former while it increased
the permeability of the clay colloids. The effect of the action of lime on both
humus colloids and other colloids was to increase ease of cultivation of the soil.
In case of humus soils the addition of lime was especially favorable to nitrogen
fixation and nitrification.

The methods of investigating the soluble soil colloids are described.

Soil evaporation, G. H. True (Nevada Sta. Bul. 731, pp. 32, 33).—In experi-
ments with jacketed tanks sunk in the soil and given surface irrigation equal
to a depth of 6 in., "the average loss of moisture for the tanks not cultivated
was equal to a depth of 1.71 in. over the whole surface, and that from the
cultivated tanks 1.3 in., the loss by evaporation being decreased 24 per cent as
result of cultivation."

In another series of experiments "two tanks were irrigated by surface flood-
ing to a depth of 6 in., two given the same amount of water applied in furrows

17732°—No. 9—12—3
3 in. in depth, two in furrows 6 in. in depth, and two in furrows 9 in. in depth. All were given a 6-in. cultivation. The average loss by evaporation during 28-day periods was as follows: From the surface-flooded tanks, 0.985 in.; from the 3-in. furrows, 0.94 in.; from the 6-in. furrows, 0.72 in.; and from the 9-in. furrows, 0.6 in."

The water-raising capacity of soils, P. S. Kossovich (Dneen. XII. S"Peda Russ. Est.-Isp. i Vrach [Moscow], p. 63; i abs. in Zhar. Opytn. Agron. (Russ. Jour. Expt. Landw.), 11 (1910), No. 5, p. 73).—Experiments with air-dried sand, loess clay, and muck clay soils were undertaken to study the height and velocity of the rise of water and the influence of readily soluble salts on these phenomena. Glass tubes 3 cm. in diameter were filled with the sifted soils. The sand contained 0.77 per cent of fine silt and clay particles, the loess clay 25.89 per cent, and the muck clay 27.05 per cent. The rise of distilled water, of a decinormal solution of common salt, and of a decinormal solution of sodium carbonate was observed.

The greatest height, 291 cm., was obtained in the loess clay with the solution of common salt. After the first 24 hours th water rose 82 cm. in the sand, 30 cm. in the loess clay, and 21 cm. in the muck clay. After 100 days the respective heights were 182 cm., 172 cm., and 106 cm., and at the end of 17 months 220, 250, and 109 cm. The influence of the salts was not marked on the sand but more pronounced on the clays. Common salt hastened the rise of the water while sodium carbonate impeded it.

Lysimeter experiments, S S. Peck (Hawaiian Sugar Planters’ Sta., Agr. and Chem. Bul. 37, pp. 5–38, charts 3).—This bulletin reports the results of 2 series of lysimeter experiments to study the effect on the formation of nitric nitrogen of various forms of lime on acid wet manka (upland) soil, and of various fertilizer salts alone and in combination on an alkaline dry maku‘i (lowland) soil. Mechanical, chemical, and bio-chemical analyses of the soils used are reported.

In an upland soil which was rich in organic matter, poor in soluble lime and potash, and acid to litmus, “calcium additions as oxide, carbonate, or sulphate, increase the nitrification of the soil nitrogen or nitrogen added as sulphate of ammonia. Calcium additions as oxide, carbonate or sulphate, increase the amounts of lime and potash soluble in water and recovered in the drainage. Calcium sulphate was more effective in all three respects than calcium oxide or carbonate. The acidity of the soil did not seem the controlling factor as regards nitrification, the water-soluble calcium seemed of greater significance. Fertilizing with water-soluble phosphoric acid and sulphate of potassium produced a slight increase in the nitrification of ammonium sulphate. Any increase in nitrification was generally accompanied by an increase in lime in the drainage.”

In a lowland soil containing a moderate amount of organic matter, rich in soluble calcium, and alkaline to litmus, “additions of fertilizing materials, as double superphosphate, tricalcic phosphate and sulphate of potassium, increased the amount of nitric nitrogen formed from the soil nitrogen. The best results in this respect followed the use of double superphosphate or tricalcic phosphate. A decrease in nitrification resulted from the use of potash and phosphoric fertilizers in lysimeters to which nitrogen as ammonium sulphate was added. The greatest depression in this respect followed the addition of double superphosphate. Liming with caustic lime depressed greatly the amount of nitric nitrogen obtained from sulphate of ammonia. No difference was observed between the nitric nitrogen in the drainage obtained from equal applications of nitrogen as sodium nitrate and calcium nitrate. Both nitrate fertilizations yielded less nitric nitrogen in the drainage than was obtained from an equal amount of nitrogen as ammonium sulphate.”
Fertilizer experiments, C. C. GEORGESON (Alaska Stas. Rpt. 1910, pp. 33, 34, 49, 50).—This is a brief account of fertilizer experiments on barley and oats at the Rampart Station.

"The fertilizers were sodium nitrate, superphosphate, potassium sulphate, and stable manure, each plat being compared with an unfertilized plat seeded with the same variety of grain and in the same manner. The result shows that when the three important elements of plant food are mixed in proper proportion the yield is better under normal conditions than when only one of them is used, and the variations which always occur in field fertilizer experiments also occur here. The important point is that the soil needs fertilization. It has been mentioned in former reports that whenever the brush and moss and dead vegetation of all kinds which cover the surface have been thoroughly burned then the soil usually yields a large first crop, but whenever, on the other hand, the surface has not been well burned the crop is usually poor [E. S. R., 23, p. 103]. There are two reasons for this; one is that the ashes which result from the burning are a valuable fertilizer in that they furnish plant food immediately available, and the other reason is that when the burning is not well done much of the moss remains, which makes the soil acid, and the acid is a poison to the crop. Now, it has been demonstrated in these experiments that even though there has been a thorough burning, followed by a heavy yield, the fertility which resulted from the added plant food in the ashes soon becomes exhausted, and to continue with good crops fertilizers must be added.

"Alaska soils are not rich. Frequently statements from travelers and other observers are seen to the effect that the soil must be exceedingly rich in plant food to judge from the height of the grasses and the luxuriance of some of the vegetation, but such a conclusion is not warranted. Grasses will sometimes grow rank on an almost barren gravelly soil because they have plenty of moisture and they are adapted to the climate and to the conditions. The virgin soil in the interior is everywhere frozen to an unknown depth or to bedrock. In this state of refrigeration there can be no activity of the organisms which aid in the formation of mold and the manufacture of plant food from the organic matter, and what plant food the soil may hold is in a large degree insoluble, and therefore not available for plants except by a long and slow process of weathering. For this reason the soil soon becomes exhausted, and fertilizers are necessary.

The law of the minimum and its applications, E. A. Mitscherlich (Landw. Vers. Stat., 75 (1911), No. 3-4, pp. 231-263; abs. in Ztschr. Angew. Chem., 24 (1911), No. 37, p. 1776; Chem. Zentbl., 1911, II, No. 14, pp. 1056, 1057).—Reviewing the results of pot experiments by Wagner and others, as well as of a series of sand cultures carried out by the author according to the Hellriegel method, the conclusion is reached that the law of the minimum is a logarithmic function and can not be established by fertilizer experiments as ordinarily carried out. The more exact sand culture method of Hellriegel is necessary for this purpose.

The use of artificial and chemical manures [on tea] (Indian Tea Assoc., Sci. Dept. Quart. Jour., 1911, No. 2, pp. 5-14).—This article discusses the fertilizing of tea with the various materials available for this purpose in Assam.

Effect of fresh and well-rotted manure on plant growth—second report, E. B. Fred (Virginia Sta. Rpts. 1909-10, pp. 132-158, pl. 1, figs. 7).—In continuation of previous experiments (E. S. R., 21, p. 418) it was found that "denitrification is most active when fresh manure is applied just at time of seeding. Very little, if any, harmful effect from denitrification could be observed in the second crop. In a clay soil the second crop seems to have been helped by the addition of fresh manure. In a loam and sand mixed the fresh manure acts
in about the same way. In wood humus pure cultures of *Bacillus denitrificans* seemed to have a slight harmful effect, even in the second crop.

"The growth of well-inoculated legumes did not seem to be affected in any way by the presence of denitrifying bacteria. Fresh manure, whenever applied to soy beans, showed an increase in yield. This increase in yield was most prominent in a clay type of soil.

"All the samples taken from different types of soil used had the power to destroy nitrates when transferred to Giltay and Aberson's culture media. The power of destroying nitrate was most prominent in soils to which fresh manure was applied and least where well-rotted manure was applied. An increase in the number of bacteria per cubic centimeter was generally followed by a decrease in yield. The harmful effect of fresh manure was most apparent when applied to open, sandy soils.

"Carbon bisulphid apparently stimulates plant growth in a very active manner. The use of carbon bisulphid caused an increase in yield of almost 100 per cent.

"Heavy applications of fresh manure in a clay loam caused a marked falling off in yield.

"Laboratory studies show that *B. denitrificans* grows rapidly on almost any culture medium: on Giltay and Aberson's under aerobic conditions. It converts the citrate into carbonate, thus producing an alkaline reaction. Within 14 days, at a temperature of 30° C., *B. denitrificans* will liberate virtually all of the nitrate that may be present in a Giltay and Aberson's culture medium. On solid media containing large amounts of nitrate *B. denitrificans* grows luxuriously and the gas evolved splits the agar or gelatin. This is best seen on glucose formate agar. *B. denitrificans* forms two soluble enzymes—oxidase and peroxidase."

The loss of nitrogen from thin layers of manure on the soil, J. Jánnes (Diss. Hanover, 1910; abs. in Zentral. Agr. Chem., 12 (1911), No. 8, pp. 521-528).—The observations here reported were made on manure spread on soil in open and closed glass dishes.

The results in both series of experiments show that the loss of ammonia depends to a large extent upon the stage of decomposition of the manure. When the manure contained a large amount of ammonia the loss was quite large when the manure was spread on the soil. When the manure was kept moist after being spread on the soil the loss of ammonia was insignificant.

The availability of the insoluble nitrogen in certain commercial fertilizers, B. L. Hartwell and F. R. Pember (Journ. Indus. and Engin. Chem., 3 (1911), No. 8, pp. 584-586).—The availability of the nitrogen of the water-insoluble residue of 12 brands of commercial fertilizers was compared with that of dried blood and nitrate of soda in pot experiments with a succession of oats, millet, and oats. Determinations of the availability of the nitrogen by the neutral permanganate of potash method are also given.

The results show that in these fertilizers, which were of high grade, the availability of the water-insoluble nitrogen was practically equal to that of dried blood and that the results by the potassium permanganate method agreed quite closely with those of the pot experiments.

Preliminary investigations on the preservation of lime nitrogen in the Tropics and the changes in form which it undergoes, C. J. Milo (Meded. Proefstat, Java-Suikerindus., 1911, No. 11, pp. 311-636; Arch. Suikerindus. Nederlandsch-Indië, 19 (1911), No. 29, pp. 983-1035; abs. in Chem. Abs., 5 (1911), No. 22, pp. 3714, 3715).—This article reports the results of experiments during 1910 to determine the water-soluble nitrogen, hygroscopicity, and changes in
form of lime nitrogen under Java climatic conditions. The sample experimented
with contained 50.89 per cent calcium cyanamid and 17.8 per cent nitrogen.

It was found that from 91.2 to 94.2 per cent of the nitrogen was soluble in
water. The gain in weight when exposed to the air in thin layers was from 30.3 to 45.3 per cent and the loss in nitrogen from 1.3 to 2.6 per cent. A
chemical study indicated the formation of the following products in the stored
material: Monobasic calcium cyanamid (Ca(CXNH)₂); dibasic calcium cyana-
mid (CXN(CaOH)₂); calcium cyanamido carbonate (CaC₂N₂O₄); cyanamid
(H₂CNO); dicyandiamid (H₂C₂N₂); urea (H₂CON₂); unidentified nitrogen com-
pounds; ammonium carbonate ((NH₄)₂CO₃); and ammonia (NH₃).

In warm, damp climates, like that of Java, which favor the decomposition of
lime nitrogen the author recommends that the product be purchased as shortly
as possible before using, that it be stored in a dry place, and that at little
surface as possible be exposed to the air.

The production of sulphate of ammonia in the year 1910, C. G. Atwater
(Amer. Fert., 35 (1911), No. 6, pp. 21–27).—Statistics of production are given
and the status of the industry during 1910 is discussed.

It is stated that the world's production of ammonium sulphate during that
year was 1,652,068 metric tons (of 2,204.6 lbs.). Of this England produced
374,925 tons, Germany 373,000 tons, and the United States 105,143 tons. Of the
total recoverable ammonia England actually recovered 57 per cent, Germany
93 per cent, and the United States 17 per cent. England and Germany lead
the United States not only in the proportion of recoverable ammonia which
they save but also in the rate at which this figure is increasing. "The United
States cokes nearly as much coal as both countries put together, yet produces
less than one-sixth as much ammonia, and has to import sulphate to make up
this deficiency in part in order to satisfy the demands of agriculture."

The chemical constitution of Thomas slag, L. Bernardini (Rend. Soc.
Chim. Ital., 2, ser., 2 (1910), pp. 133–135).—This is a brief discussion of this
subject, based mainly upon the work of others.

Note on the occurrence of manganese in soil and its effect on grass, F. B.
4, pp. 354–360).—This has already been noted from another source (E. S. R.
23, p. 720).

The function of manganese as a fertilizer, L. Bernardini (Rend. Soc. Chim.
Ital., 2, ser., 2 (1910), pp. 135–137).—This is a brief discussion of this subject,
based mainly upon the work of others.

Mineral resources of the United States, calendar year 1909.—Part II.
Nonmetallic products (U. S. Geol. Survey, 1911, pp. 332, figs. 6).—This is the
usual detailed report on this subject. The chapters of greatest agricultural
interest are those relating to lime, gypsum (E. S. R., 25, p. 218), and phos-
phates (E. S. R., 25, p. 217). In these articles the statistics are brought up to
the close of the year 1909.

It is stated that the total production of lime in 1909 was 3,472,552 tons, of
which 595,517 tons valued at $1,630,633, was used for fertilizing purposes, and
1,904,863 tons valued at $8,390,353, was used for building purposes. A detailed
classification of the chemical uses of lime is given.

(1911), No. 3, pp. 74–84, 91–101).—The laws and regulations controlling the in-
spection and sale of mixed fertilizers in Florida are given, with notes on valu-
ation and tabulated analyses of 208 samples of fertilizers examined during the
year 1911.
Analyses of fertilizers and cotton-seed meal, fall season, 1910, and spring season, 1911, B. W. Kilgore et al. (Bul. N. C. Dept. Agr., 32 (1911), No. 8, pp. 157).—This bulletin contains analyses of fertilizers and cotton-seed meal collected by the fertilizer inspectors of the state department of agriculture during the fall of 1910 and spring of 1911, as well as a list of brands of fertilizers registered for sale in 1911.

AGRICULTURAL BOTANY.

An introduction to vegetable physiology, J. R. Green (London, 1911, 3. ed., pp. XXII+470, figs. 182).—This new edition is the result of 10 years' experience with the older work and embodies many changes in the text. Parts of the book have been rewritten to incorporate the results of recent investigations, and other parts rearranged, to the manifest advantage of the method of treatment. This is especially true of the chapter on the energy of plants, which now includes the material formerly discussed under respiration. An attempt has been made to correlate more closely the structure of plants with their physiological needs and to consider their general relations to environment. The fundamental idea of the book is the plant as a living organism having certain properties and powers, and how it meets its requirements.

Investigations on the rôle of fats in the lower plants, J. Dauquilé (Mém. Soc. Sci. Phys. et Nat. Bordeaux, 6. ser., 5 (1910), No. 1, pp. 51-138, dges. 2).—This is a detailed account of investigations on the physiological rôle of fats in molds and other plants, a preliminary account of which has been previously noted (E. S. R., 20, p. 735).

Studies of variation in plants, H. H. Love (New York Cornell Sta. Bul. 297, pp. 533-677, figs. 70).—The results are given of a study made to determine the extent to which fluctuating variability is influenced by environmental factors and especially by food supply. The data presented are those secured in a study of 2 generations of peas, 2 varieties of buckwheat, and 1 crop of corn.

In general the means were found to increase as the fertility of the soil was increased. The standard of deviation showed an increase in most cases as the food supply was increased. The coefficients of variability were affected differently for different characters. In about one half of the characters studied the coefficient was increased, while in the other half it was decreased. Certain characters of a species or variety were found much more variable than others. The coefficients of correlation in general decreased as the food supply was increased.

The results obtained in this investigation led the author to think that there is a greater degree of variation and a lesser degree of correlation among plants grown on very rich soil. The data given are not held to prove this conclusion, but rather are offered as evidence in favor of it.

A brief bibliography of this subject is appended.

The F, heredity of size, shape, and number in tomato leaves.—I, Seedlings. II, Mature plants, B. H. A. Groth (New Jersey Sta. Buls. 238, pp. 38, pls. 9, figs. 8; 239, pp. 72, pls. 9).—In these bulletins descriptions are given of the grosser characters which distinguish the foliage of a number of types of tomatoes, and a report is made on the heredity of such characters in the first generation. This is in continuation of a series of studies previously reported (E. S. R., 23, p. 528).

The author found that the leaves of tomato types differ in many characters of size, shape, and number, in the cotyledons, first leaves, and large leaves. Practically all characters studied tend to exceed the mean between the values
of the parents in the F1 of the cross, the leaves of the cross tending to be longer, narrower, and to possess a greater number of segments than the mean between the parents or than either of the parents themselves. In other words, the crosses tend to be more vigorous than the parent plants. The combination of the same two characters in different crosses may or may not produce the same results in the F1 of the crosses, while reciprocal crosses frequently differ in the young plants, but more rarely in the old plants, in respect to the heredity of characters of size, shape, and number. The size and probably the shape of the seed of the female parent is found to produce an effect on the heredity of size and shape, in the F1, of the cotyledons, which may or may not extend to the first leaves. The dwarfs react in the character of size in the F1 crosses, as if they had larger cotyledons.

The infection of root hairs by means of Bacillus radicicola, E. B. Fred (Virginia Sta. Rpts. 1909-10, pp. 123-137, figs. 36).—A description is given of the method of infection of leguminous plants by B. radicicola, the author showing that after entrance is gained into the root hair the tubercle bacteria multiply rapidly, forming a thread-like growth from the point of infection along the hair into the inner cells. The course of infection is not marked by a well-defined tube, as some authors have described, but by the infecting strand in which the separate bacteria can be distinguished. The course of infection is generally along the center of the root. Soon after infection a conical mass of cells is formed, which develops into the tubercle and pushes out the overlying cortical parenchyma and epidermis. Though the cortical cells are somewhat compressed, the epidermis is not ruptured nor does the tubercle burst out of the side of the root. Older tubercles sometimes appear as though formed exogenously, but if their development is carefully traced it will be found that they were formed endogenously.

Studies were made of 4 separate species of leguminous plants to determine the variation in the shape and size of the bacteroids. These forms are described, and the author considers them stages in the development of the bacteria and not degeneration nor transformation forms. In the development of the bacteroids the author noticed that certain portions were not stained by the ordinary methods and these are considered as being vacuoles. This is also believed to be a definite period of growth and not a sign of polymorphism of the bacteroid.

The plants representing different periods of growth as well as the organism causing the root tubercles are figured and described.

FIELD CROPS.

[Field crops experiments in Alaska], C. C. Georgeson et al. (Alaska Sta. Rpt. 1910, pp. 14-16, 31-33, 36-39, 44-49, 50-52, 54-58, 62, 63, pls. 9).—At the Sitka and Rampart stations sprouted potatoes yielded much more abundantly than those not sprouted. At the Rampart Station the 6 best varieties are the following: Extra Early Triumph, Extra Early Eureka, Extra Early Pioneer, Gold Coin, Irish Cobbler, and Early Ohio. At the Fairbanks Station 11 acres were planted to potatoes but only 3½ acres, on newly cleared birch land on a hillside with a southern exposure, gave satisfactory yields. The 3 varieties giving the highest yields are Eureka, Gold Coin, and Red Early Ohio. Gold Coin is mentioned as among the highest yielding varieties at all these stations.

At the Rampart Station attempts are being made to secure an earlier and higher yielding barley by crossing. Kharkov winter wheat came through the winter with a 90 per cent stand and matured a fair crop. All the varieties of winter rye so far tried have lived through the winter and matured grain, but
winter emmer and barley did not give satisfactory results. Nearly all the
varieties of spring barley tried ripened before frost occurred. A description
is given of each of the different varieties of barley grown and data show the
results of various crosses made. Tabular statements are given comparing the
adaptability of the various oat and winter wheat varieties grown and also
the growth and hardiness of certain grasses and legumes. All of the grasses
and legumes grown survived the winter in excellent condition. Timotheysur-
ved the winter in perfect condition but the summer's growth was short and
spindling. Oat hay at Calsinsky Bay and Kodiak yielded 1½ and 2½ tons
respectively per acre.

At the Fairbanks Station the following grains matured: North Finnish
Black oats, oats No. 637, and Sixty-day oats. Barleys which matured are
Hansen No. 279; Manshury; barley No. 19,851, a beardless and hull-less variety;
barley No. 19,852, also a beardless variety; and even Hannah, a two-rowed
rather late barley matured on a favorably situated plat. Spring wheat was a
failure, but winter wheat was more successful. Kharkov winter wheat sur-
vived the winter with a 50 per cent stand and was ripe by August 15. Winter
rye No. 19,556 survived the winter in better condition than wheat and was
ripe by August 10. Experiments with grasses have so far proved unsatisfactory.

The proper culture of grain and the maintenance of soil fertility in Alaska
are also discussed.

[Guam forage crop and grain storing experiments], J. B. Thompson
1).--At the Guam Station the sorghums have surpassed all other crops under ob-
servation for forage purposes. Kafir corn on new soil has yielded about 7½ tons
of green feed per acre. The first crop was obtained in about 3 months during the
dry season, but 2 successive ratoon crops at intervals of about 6 weeks pro-
duced about as great yields. Guinea grass (Paniceum maximum) made little
headway on poorly drained soil during a wet season, but yielded 12 tons per
acre on soil lower in fertility, after the roots had been taken up and subdivided.
Johnson grass (Sorghum halepense) made a satisfactory growth, but showed
its usual tendency to spread. Large water grass (Paspalum dilatatum) gave
excellent results throughout both the wet and dry seasons and did well on poorly
drained soil during long periods of heavy rainfall. Alfalfa did well during the
dry season but its success during the rainy season is still undetermined. Cow-
peas and velvet beans have also made a good growth.

A description is given of an air-tight metal tank, hermetically sealed by a
heavy oil such as coconut oil, for storing grain. The problem is to avoid injury
from weevils and atmospheric moisture. Corn stored in such a tank December
16 showed no deterioration 6 months later.

[Nebraska field crops experiments] (Nebraska Sta. Rpt. 1910, pp. IX-XIV,
XX-XXIV, XXV, XXVII).--Data obtained during the year are reported.

In a test of the water requirements of corn, narrow-leaved types selected from
Hogue Yellow Dent proved more drought-resistant than broad-leaved types of
this variety. During 1905-9 plants averaging 1,300 and 992 sq. in. in leaf area
yielded 43.6 and 52.1 bu. of corn per acre, respectively.

Since 1903 the produce of selected Turkey Red winter wheat plants has been
kept separate, being compared for 4 years under nursery conditions, and a like
period in the field. Of the 26 strains tested in the field the lowest 3 averaged
30 bu. per acre, the best 3 averaged 40 bu., and the check plats of the original
wheat 35 bu. Eleven years' results indicate that practically equal yields of
wheat follow plantings of the lightest and heaviest seed as separated by the
fanning mill. Six years' work with oats gives similar results. The lightest
fourth of the light seed and the heaviest fourth of the heavy seed were used.
Studies as to the competition of cereals indicate that "a larger percentage of plants originating from shrunken seed than plump seed are crowded out." This indicates the importance of natural selection in maintaining vigor and yield.

In a test of 16 varieties of corn Hogue Yellow Dent and Leaming produced
8,530 and 7,155 lbs. of dry matter per acre, respectively, these being the highest yields.

The amounts of organic matter and nitrogen added to the soil by alfalfa and clover roots were determined. In 1 field 2.3 tons per acre of organic matter were added by the first 8 in. of alfalfa roots, and 0.9 ton by the 3 in. stubble. Another field contained 3 tons per acre of organic matter in the first foot of soil, containing 125 lbs. of nitrogen, and another field 1-year old 2 tons of organic matter and 72 lbs. nitrogen. A clover field sown in the spring showed in August 1.25 tons of organic matter in the roots and 44 lbs. of nitrogen, and 2.25 tons of organic matter and 137 lbs. of nitrogen in the tops. An old alfalfa field showed 2.55 tons of organic matter and 105 lbs. of nitrogen per acre in the first foot of soil, and 2.05 tons of organic matter and 65 lbs. of nitrogen in the next 10 ft.

Five crops of winter wheat produced on summer tilled land at the North Platte substation show that "a fair average of wheat planted at the proper time and of the standard variety is 46.7 bu. per acre. This is 6 bu. more than twice the yield from land not summer tilled."

Two common spring wheats have averaged 20.96 bu. per acre or 2 bu. less than the 4 leading durum varieties during the past 4 years. Among oat varieties Kherson held first place without a close rival until 1908 when the Burt oat was introduced. Since that time the yields have been about equal. Common six-rowed barley averaged 39 bu. per acre on summer tilled land as compared with from 20 to 25 bu. on land continuously cropped. It has proved the best variety for this region.

On disked corn fields oats yielded 38.6 bu. per acre, barley 35.3, emmer 34.9, durum wheat 23.4 and hull-less barley 18.4 bu. during the past 4 years. As compared with broadcast seeding and harrowing "drilling has increased the yield of spring wheat 7.4 bu. per acre, of barley 7.7 bu., of oats 10.3 bu. and of emmer 10.8 bu."

During the past 6 years from 10 to 35 varieties of corn have been tested with an average yield of 25 bu. per acre and a range from almost a failure to 52 bu. per acre. Substation Calico, a medium-size corn, may be considered one of the best.

A brief progress report of rotations and tillage methods indicates that summer tillage has increased the yield of spring grain but not sufficiently to warrant urging its general adoption. It has more than doubled the yield of winter wheat. Corn has usually yielded more heavily with continuous cropping but in 1910 it yielded 2½ times as much on summer tilled land as on any of that continuously cropped.

Soil moisture studies indicate that the moisture content may be increased to an indefinite depth depending on the character of the soil, precipitation, and tillage. Water to the amount of 6 or 8 acre inches may thus be accumulated.

Alfalfa growing is discussed and directions are given for securing a sorghum crop.

A list is given of the species and varieties of clovers, mainly from California and Nevada, now being tested. Among the annuals *Trifolium arvense* and *T. obtusiflorum* made the most vigorous growth and among the perennials *T. productum* and *T. vomorhjoldii* are given special mention. *T. suaveolens*, S. P. I. 25,177, was well above ground and green within 3 days after planting and is recommended for trial in the southern part of the State.

Land plowed in 1907, left fallow during 1908, and seeded to Kubanka wheat in the spring of 1909, yielded 4 bu. per acre. The soil was a heavy clay not adapted to dry farming but representative of the foothill region of the Truckee Valley.

Two irrigations before heading and 2 after heading, aggregating 1.892 ft. of water, were followed by a higher yield of White Australian wheat, 40.5 bu. per acre, than were larger or smaller amounts of water differently applied. Similarly 82.2 bu. of Siberian oats followed 2 irrigations before heading and 3 after heading, aggregating 2.139 ft. of water. Approximately equal yields of Kubanka wheat, about 31.5 bu. per acre, followed applications of 1.447 and 0.767 ft. of water. Seven tons of alfalfa per acre were secured after an application of 2.186 ft. of water as compared with smaller yields from both smaller and greater applications of water. An application of 3.042 ft. of water was followed by a yield of 21.5 tons of roots per acre.

The utilization of logged-off land for pasture in western Oregon and western Washington, B. Hunter and H. Thompson (U. S. Dept. Agr., Farmers’ Bul. 462, pp. 20, figs. 5).—Discussion of the extent and need of utilization of logged-off land are followed by directions for burning over and planting such lands for pasture. The adaptability of each of a number of grasses, clovers, and pasture mixtures for this purpose is discussed and directions are given for seeding and managing the pasture. The use of Angora goats for killing brush is advocated.

*Alfalfa at the Pennsylvania State College, F. D. Gardner* (Pennsylvania Sta. Rpt. 1910, pp. 32-36, pl. 1).—Continuing previous work (E. S. R., 18, p. 232), these pages state briefly the methods used in obtaining a stand of alfalfa on a small field at the station. At 14 cuttings made during the 5 years 1905–1909, this field gave an “aggregate yield of 17.06 tons of air-dry hay per acre or an average of 3.41 tons per year.”

A test of applications of lime, barnyard manure, nitrate of soda, dissolved rock, muriate of potash, and inoculated soil failed to indicate any advantage from the application of lime, but the field was found to have been limed not long before the date of seeding. No marked differences in results followed the use of the different fertilizers singly or in various mixtures.

The relation of climatic factors to the water used by the corn plant, T. A. Kiesselbach and E. G. Montgomery (Nebraska Sta. Rpt. 1910, pp. 91–107, figs. 6).—To study the relation of the water content of soils to plant growth and transpiration and of climatic factors to transpiration, corn plants were grown in large galvanized iron potometers (fig. 1) located in a cornfield and exposed to the general climatic conditions which prevailed in the field.
“The potometers were 3 ft. deep and 16 in. in diameter. Each contained the equivalent of 260 lbs. moisture-free silt loam soil. A 3-in. layer of gravel (E) served to prevent surface evaporation. Rain was excluded by means of a galvanized iron lid (D) having a 4-in. opening for the plant. This opening was covered with oil cloth, closely fastened about the cornstalk. Buried in the soil and connected at the top with a covered 6-qt. can was a spiral coil (B) made of ½-in. brass tubing 15 ft. in length and perforated every 8 in. All water was added through the small can (C) and distributed uniformly throughout the soil by means of the perforated coil.

Five different degrees of soil saturation were maintained throughout the growing season. This made 5 sets of 4 plants each, varying from 35 to 100 per cent saturated soil. Saturation was regarded as the amount of water retained by the soil after drainage ceased from water poured on the soil surface. It required 100 lbs. of water to saturate the 260 lbs. moisture-free soil in each potometer. The 5 degrees saturation maintained were 100 per cent, 80 per cent, 60 per cent, 45 per cent, and 35 per cent.

The daily transpiration was determined by loss in weight. The soil saturations were kept fairly constant by restoring, each evening, the exact quantity of water transpired during the day. When the loss was likely to be large, water was added twice each day.

In connection with these transpiration determinations accurate records were obtained in the immediate vicinity by means of standard self-recording instruments of those climatic factors which were likely to affect the rate of water loss.

The daily evaporation rate from a free-water surface was obtained by averaging the losses in weight from six 1-gal. glazed stone jars in which the water level was daily restored to 1 in. below the top of the jar. These jars were placed at different altitudes, ranging uniformly from the ground up to 10 ft. above the ground. By taking the average evaporation from free-water surfaces distributed in this manner, data were obtained which may be compared with the transpiration from corn plants, the leaves of which vary in their height above ground.

In one experiment the evaporation rate was obtained by averaging the water loss from 5 Livingston porous clay cup evaporimeters.

Comparative data were also secured as to the wind velocity in a cornfield at altitudes of 4 ft. and 10 ft. above ground.”

It was found that “the optimum soil saturation for growth was from 60 to 80 per cent. The percentage of ear increased as saturation decreased down to 45 per cent, though the largest actual weight of ear was produced at 60 per cent and the greatest total dry weight at 80 per cent.

Least water per gram dry weight was used in 45 to 60 per cent saturation. The percentage of leaf area to dry weight was least under the most nearly optimum conditions.

When the hourly fluctuation in evaporation of free water was compared with the transpiration of a corn plant, they were found to fluctuate in almost perfect accord, the transpiration tending neither to lag nor to accelerate. This indicates that ‘transpiration’ is essentially ‘evaporation.’

Transpiration records for daily or weekly periods gave similar results up until the latter part of the season, when plants began to ripen. Then evaporation exceeded transpiration.

The transpiration for the 12 hours of day was about 13 times greater than for the 12 hours of night.”

Correlation studies of corn, E. G. Montgomery (Nebraska Sta. Rpt. 1910, pp. 108–159, figs. 4).—The object of this investigation was to secure data on (1)
the correlation between parts of the corn plant and the value of certain combinations of characteristics, (2) the modifications which take place in the corn plant as a result of a change in environment, and (3) the relations between the amount of water used, the leaf area, and the growth of the plant.

Observations were made on many individual plants during 1902 and succeeding years. Tables present data dealing with the following points: Leaf area, height of stalk and ear, number of nodes, ear nodes, length of shank, weight of stalk, ear, and total plant, ratio between weight of stalk and weight of ear, and ratios of leaf area to total weight, weight of ear, and weight of stalk.

It was found that when individual plants were considered there was no marked relation between leaf area and weight of corn produced or total weight of plant. In different varieties, however, there was quite a difference in the ratio of stalk to ear, the ratio being 0.74 in the case of Pride of the North and 1.15 in Hogue Yellow Dent. The amount of leaf area to 1 gm. of dry weight was also found to vary, ranging from 2.3 sq. in. for Minnesota No. 13 to 2.66 sq. in. in case of Hogue Yellow Dent.

Corn grown from Iowa seed was taller and made a larger stalk than that grown from Nebraska seed, in an acclimatization test. Tables show the degree of correlation between the different parts of the corn plant.

The author draws the following conclusions in regard to useful characters under observation: (1) "A low relative leaf area seems desirable." (2) "Assuming high proportion of corn to be desirable, a short shank is preferable." (3) "Selection of high or low ears does not affect yield." (4) "Medium in stoutness of stalk would seem best."

Data given show that the relative size of plants was not transmitted to any degree, and the author states that variation in size of plant is not inherited but is due to some local cause, which indicates that size of plant is so modified by local conditions that potential qualities can not be judged from the individual. Taking plants as found under field conditions no characters have been found closely enough correlated to indicate ability to yield. The inherent characters can only be determined by a study of a sufficient number of progeny.

Data collected during a 3 years' test show the relation of water loss to leaf area and dry weight. The plants experimented with were grown in potometers under uniform conditions as to fertility, quantity of soil, and available water. The results show that in various types of corn the amount of water transpired by the plant is correlated to some extent with leaf area.

Genetic correlation and spurious allelomorphism in maize, R. A. Emerson (Nebraska Sta. Rpt. 1910, pp. 58-90, figs. 9).—A discussion is given of color correlations in general showing that it is often very difficult to determine whether characters are genetically correlated or not. In crosses of varieties of green-podded, green-leaved beans with yellow-podded sorts also having green leaves, the F1 generation had green pods and leaves and the F2 generation showed typical Mendelian behavior, thus giving evidence that pod color and leaf color in beans are not genetically correlated. However, in another cross between the green-podded, green-leaved sort with a variety bearing "golden" leaves as well as yellow pods, the F2 generation separated into 2 distinct classes, showing correlation.

Tables state the results of work done in trying to find correlated colors in maize. The F1 generation plants were taken from the open pollinated parent and the data show the color of cob, pericarp, and in some cases of husks, silks, and anthers. The F2 generation was selected from the self pollinated F1 generation and gives similar data in regard to colors. "In every case but 4, included in the table, only 2 types occurred in the F2. One type always had
all the dominant colors of the parts in which the 2 types differed in color, and the other type all the recessive colors. There was apparently an absolute correlation (presumably a genetic correlation) between color of cobs, pericarp, husks, silks, and anthers.

Data are also presented showing spurious allelomorphism in maize and a few cases in which a dominant color of the cob is allelomorphic to a dominant color of the pericarp. The author considers that spurious allelomorphism occurs with respect to cob and pericarp colors in maize and bases his strongest evidence upon the genetic analysis of the F1 plants made possible by crossing them with plants lacking genes of the characters concerned.

A comparison is made of genetic correlation and spurious allelomorphism and the relation of each to the way in which genes are associated in the gamete is discussed at length. Attention is called to the possible genetic correlation of sizes and other characters, in which there is noted an interesting case of correlation in maize between dwarfness and broad leaves, the presence of stamens throughout the ear, club-shaped tassels, and defective anthers. This correlation was observed in 3 families of corn in 1910. Considering the 3 families together there were 107 of the tall monoecious plants and 25 of the dwarf andromonoecious ones at the time the plants had finished their growth, thus showing definite correlation. In 2 of the families height characters were found to be sharply segregated.

The author discusses his observations with respect to the possible behavior of the genes which represent the characters of maize in the chromosome.

Muslin screens to keep corn from crossing, L. Carrier (Virginia Sta. Rpts. 1909-10, pp. 119-123, figs. 4).—These pages describe the method of construction of muslin screens used for the prevention of cross pollination of corn on adjacent experiment plats.

During 1908 the muslin partitions were 10 ft. high and the plats were roofed in, but with this method heat collected and weakened the stalks so that some of them broke of their own weight. In 1909 the same partitions were raised 3 ft. from the ground and no covering was used. This method apparently did not weaken the plants and there was "little evidence of crossing of varieties—no more than we found in our isolated, pure bred plat."

During some of the heaviest gales, little indication of air currents inside the inclosure was observed. The author notes that there was no outside corn immediately adjoining the plats and believes that if there had been, pollen would doubtless have been blown over into the inclosure. Boone County White and Leaning were used and crossing would have been quite noticeable.

Göttingen oats, I, II, III, IV. O. Tornau (Jour. Landw., 59 (1911), No. 2, pp. 137-184).—This article describes with great detail the morphological characters of these different varieties of oats, originated at the Göttingen Experiment Station, and the characteristics of each variety of particular value to the farmer and plant breeder are also enumerated.

The sweet potato, B. H. A. Groth (Contrib. Bot. Lab. Univ. Penn., 4 (1911), No. 1, pp. 104, pls. 54).—This work is a review of the historical records of Ipomoea batatas, made for the purpose of furnishing a working basis for future experimentation with its many varieties. A chapter each is devoted to the following topics: Origin and history, economic importance, the structure of I. batatas, and classification of varieties.

Summary of experiments in the culture of Sumatra tobacco under shelter, W. Frear and E. K. Hibshman (Pennsylvania Sta. Rpt. 1910, pp. 233-243, pls. 2).—After a discussion of the cultivation, harvesting, and cost of production of Sumatra tobacco under shelter, the authors conclude that its cost of production
on a commercial scale ranges from 45 to 75 cts. per pound for cured leaf. A shelter tent experiment at Cocalico proves that a leaf can be produced which approaches the average imported Sumatra in color, luster, fineness of vein, wrapping capacity, and burn. A strain has been developed which is adapted to the Pennsylvania sandy loam and to the particular climatic growing conditions.

1909 experiment with Sumatra tobacco under shelter, E. K. Hirschman (Pennsylvania Stu. Rpt. 1910, pp. 236-238).—Using the Greider strain of Connecticut Sumatra seed a crop of 377.5 lbs. of stripped leaf was produced in 1909 at a cost of $262.67. The cost of handling the cured leaf, sweating, sorting, losses of weight during the process and interest on the investment brought the net cost per pound in this unfavorable year to about $1.

Roumanian wheat, A. Zaharia (Der Rumänische Weizen. Bucharest, 1911, pp. VII + 177, map 1).—This is a controversial article with reference to the relative merits of Hungarian and Roumanian wheats. In connection with the discussions presented, considerable experimental data are given, mainly with reference to the crops for the years 1900-1908.

The eradication of quack grass. J. S. Cates (U. S. Dept. Agr., Farmers' Bul. 464, pp. 11, figs. 6).—Descriptions of the underground stems of quack grass (Agropyron repens) and of the varying development of these roots in cultivated fields, meadow lands, and pasture land are followed by directions for the eradication of the pest, either by plowing the sod in midsummer and diskling about once in 10 days until fall or by diskling alone.

HORTICULTURE.

[Horticultural investigations in Alaska], C. C. George.son et al. (Alaska Stus. Rpt. 1910, pp. 10-11, 16-29, 53, 58, 59, pls. 3).—The work of greatest interest at the Sitka Station during the past year was the cultivation of hybrid strawberries (E. S. R., 23, p. 639). An increased number of promising varieties was secured. Thus far 166 out of 1,800 fruiting plants have yielded market-size fruit and 35 plants have produced larger berries than the average market variety. Crossing the cultivated forms with a native wild berry has, with a few exceptions, improved the flavor. This work is discussed and illustrations are given of a number of the hybrid types secured.

Notes are given on the condition and behavior of vegetables, orchard and small fruits, and ornamentals being tested at the station. The test orchard, consisting of a few trees each of a number of varieties of apples, as well as some cherries and plums, is making but slow progress. After several years of observation it seems probable that apples of any of the varieties now known and cultivated can not be successfully grown in any part of Alaska. Although cherries have made better growth than apples, nearly all of them blooming in the spring and in favorable seasons fruiting a little, it is considered doubtful whether they can be made to fruit in any part of Alaska when grown in the open. The plum trees are not yet large enough to fruit, but judging from their growth it seems probable that they will not be successful. Of the small fruits, currants, gooseberries, and red raspberries do well. Black raspberries and the blackberry are complete failures in Alaska. The hybrids between cultivated and native raspberries have thus far shown no improvement over the parents (E. S. R., 20, p. 143).

Of the ornamentals tested the Japanese rose (Rosa rugosa) is in the first rank and several varieties of the Tartarian honeysuckle are next in point of vaine. Spiraea thunbergii, Berberis sp., the red berried elder (Sambucus pubens), and the mountain ash, together with a number of perennial and annual flowering plants can be grown successfully.
Cultural tests of vegetables at the Rampart Station have shown that gardening in interior Alaska differs very little from gardening in any of the Northern States. Garden seeds from specially hardy or acclimated plants are unnecessary. Peas and cauliflower have been canned with success, thus demonstrating the feasibility of local supplies of canned vegetables for the long winter months. At the Fairbanks Station nearly all the hardy vegetables were grown and gardens in the vicinity produced the usual abundance of vegetables of the finest quality. One gardener raised 16 tons of cabbages on a half acre of highly fertilized soil. The average heads weighed about 16 lbs. and the largest 33 lbs.

[Report on vegetable experiments], J. R. Thompson (U. S. Dept. Agr., Office Expt. Sta., Rpt. 1910, pp. 596–597).—Experimental work with vegetables at the Guam Station, which was established in 1909, has thus far been confined to the introduction of various vegetables and to tests with a view to obtaining better varieties than those already grown. Among the vegetables which have been successfully grown are beans, eggplants, radishes, okra, peppers, lettuce, cucumbers, muskmelons, and watermelons. Beets grew quickly until about 2 in. in diameter when the leaves were destroyed by lepidopterous insects before their presence was noted. Cabbage has thus far failed to mature heads.

Melon culture, J. Troop (New York, 1911, pp. XI+105, figs. 22).—A practical treatise on the principles involved in the production of melons, both for home use and for market, including a chapter on forcing and one on insects and diseases and means of controlling the same.

Peas and pea culture, G. C. Sewey (New York, 1911, pp. XI+92, figs. 17).—A practical and scientific discussion of peas, relating to the history, varieties, cultural methods, and insect and fungus pests, and with special chapters on the canned pea industry, peas as forage and soiling crops, garden peas, sweet peas, seed breeding, etc.

The most important measures which have been undertaken during the past ten years for the development of fruit growing and fruit marketing in Bavaria, Rebholz (Länd. Jahrb. Bayern, 1 (1911), No. 9, pp. 672–688).—A summarized review of measures which have been employed to develop the fruit industry in Bavaria, including statistics of the fruit industry in Bavaria for the year 1910.

Fruit-bud formation and development, A. W. Drinkard, Jr. (Virginia Sta. Rpts. 1909–10, pp. 159–205, figs. 106).—This comprises a study of the formation and development of fruit buds of the apple, plum, pear, peach, and cherry, started in 1908 and extended over a period of 2 years. The results of previous investigators are summarized. The methods employed in making microtome sections and micro-photographs are described in detail and the formation and development of the different types of fruit buds are shown in a series of micro-photographs with accompanying legends and discussions.

The principal stages observed in the life history of fruit buds were a prolonged period of formation during the summer, which began in the case of the Oldenburg apple during the last week in June, although the Whitaker plum, a hortulana variety did not form fruit buds until the first week in September. Development continues through the summer and fall and the flower parts are practically complete about November 1. During the winter months cytological changes are going on in the essential parts of the flowers. Rapid development of the floral organs again takes place during the few weeks previous to blossom-
ing. The time of formation of fruit buds was found to be much more variable between different varieties of plums than between varieties of apples.

From a consideration of the data as a whole the following general conclusions as applied to orchard practice are deduced: "Buds which produce the crop of bloom for the current year are formed the preceding summer; initial fruit-bud formation has its beginning during June or July, depending on seasonal conditions and the kind of fruit. The proper development of the fruit bud would therefore be influenced by factors which are brought to bear upon the tree prior to and during the period at which fruit-bud formation takes place. In the practice of such orchard operations as are designed to influence or control fruit-bud formation, it appears that such operations should be more effective in the spring and early summer than at other stages of development."

Experiments in the pollination of our hardy fruits, C. H. Hooper (Agr. Students' Gaz., n. ser., 15 (1911), No. 4, pp. 110-113).—In a brief summary of his work conducted at Wye, Kent, the author finds that the gooseberry and red and white currants fruit well under self-fertilization. In support of observations made in this country, however (E. S. R., 21, p. 636), he finds that a majority of apples, pears, plums, and cherries require cross-pollination.

Pollination of Bartlett and Kieffer pears, S. W. Fletcher (Virginia Sta. Rpts. 1900-10, pp. 213-224, figs. 14).—As a result of his previous experiments and observations on the barrenness of orchards, the author found that a great many varieties of fruits, including the Bartlett and Kieffer pears, tended toward self-sterility and that, in general, orchard planting with reference to cross-pollination was advisable (E. S. R., 12, p. 237). In order to determine suitable pollenizers for the Bartlett and Kieffer pears and to some extent for other fruits, experiments were conducted under the direction of the West Virginia Station in 1903 and at the Michigan Station in 1906 and in 1907. The methods used with other technical details have appeared in a previous paper. The present report, which summarizes the work as a whole, shows further evidence of the self-sterility of the Bartlett and Kieffer pears.

The results of hand pollinating over 8,000 Kieffer pear blossoms and about 10,000 Bartlett pear blossoms in the 3 years above mentioned show that self-sterility is the rule and that cross-pollination by insects is not general. The Anjou, Lawrence, Duchess, and Kieffer varieties proved to be satisfactory pollenizers for planting with the Bartlett, although in some seasons the Kieffer and Bartlett do not blossom simultaneously. LeConte, Garber, Lawrence, Bartlett, Duchess, Anjou, and Clairgeau were satisfactory pollenizers for the Kieffer. Although the five latter varieties do not blossom simultaneously with the Kieffer in certain years, the blossoming seasons usually overlap sufficiently.

The results of hand pollinating nearly 3,000 Gold Drop peach blossoms in 1906 showed no benefit to this variety from cross-pollination with St. Johns, Late Crawford, or Lewis. The self-fertilized fruits were perhaps a trifle superior.

The investigation as a whole has confirmed the author's previous conclusions relative to the desirability of mixed planting. No immediate effect of pollen and no differences obviously due to mutual affinity were discovered. The cross-fertilized fruits averaged about the same in size, shape, color, and quality regardless of the pollen used.

A new method of handling pollen, S. N. Green (Amer. Breeders Mag., 2 (1911), No. 1, pp. 52-54, fig. 1).—During the course of work in the pollination of a number of different fruits, the author has found that empty quinip cap-

---

sules seem to meet the requirements under almost all circumstances for gathering and storing pollen and that they are convenient to use. The anthers of the desired parent are selected as near the bursting point as possible and scarped or cut into a capsule. In a few hours the anthers in the capsule burst and when shaken the pollen scatters around and adheres uniformly over the gelatine walls of the capsule from which it can be transferred to the stigma with the usual brush or thin-bladed knife. Pollen thus inclosed retains its vitality for a long time and the capsules may be mailed to distant points without trouble. Some difficulty was experienced with the pollen of some of the Cucurbitaceae which seems to be very moist and sticky and does not readily separate from the anthers.

Relative success of different grafts, J. P. Stewart (Pennsylvania Sta. Rpt. 1910, p. 270).—The ordinary whip graft on the limbs has been compared with the side graft on the trunks in a total of over 2,200 cases. The relative success of grafting trees just set as compared with trees established by one season’s growth in the orchard was also noted.

The results show a percentage of 67.28 succeeding in case of the whip grafts and 70.03 with the side grafts; 55.65 per cent of the grafts on trees newly planted were successful as compared with 69.17 per cent on established trees. Since over half the grafts grew on the newly planted trees it appears to be good orchard practice to top-work the trees when first set and to work over the failures either by budding in August or by grafting in the following spring.

Frost fighting investigations, P. B. Kennedy (Nevada Sta. Bul. 731, pp. 21–24).—An account is given of preliminary investigations in the use of orchard heaters, conducted in the spring of 1910, including a record of temperatures, notes on the condition of different varieties of apples, methods employed, and the time of blossoming of the different varieties of apples in 1909 and in 1910.

The district street plantations in Offenbach with special reference to fertilizer investigations, G. Biesterfeld and E. Lierke (Deut. Obstbau Ztg., 1911, No. 17–18, pp. 271–300, figs. 43, maps 2).—An account is given of the development and management of street fruit tree plantings in the district of Offenbach, together with an account of fertilizer experiments which have been conducted with these trees since 1890. These experiments, which are being continued, have shown for the few years which the trees have borne fruit that judicious application of a complete fertilizer will prove profitable. The use of any single nutrient has resulted in a loss.

Lime-sulphur on peaches, and in summer control of scale on apples, J. P. Stewart (Pennsylvania Sta. Rpt. 1910, p. 268).—In continuation of his studies of lime-sulphur sprays (E. S. R., 23, p. 296), the author has found that summer-strength lime-sulphur applied on June 22 and 30 and on July 11 against the young San José scale, which had emerged first about June 18, were thoroughly effective against the young in all cases and also that each spray very materially reduced the number of adults. No further emergence of young scales was noted and a thorough examination on August 20 failed to reveal any signs of living scales whatever. A similar experiment with an apple tree about 8 years of age and badly infested indicates that it is quite possible and practicable to control San José scale on apples by summer spraying alone, though 2 or more sprays will doubtless be required.

Some new data regarding the lime-sulphur wash, L. L. Van Slyke (West. N. Y. Hort. Soc. Proc., 56 (1911), pp. 66–72).—A summarized presentation of data previously reported and noted (E. S. R., 24, p. 663).
Some new fruits, N. E. Hansen (South Dakota Sta. Bul. 130, pp. 163–200, figs. 15).—In continuation of previous reports (E. S. R., 20, p. 239) the records of a number of promising hybrids secured in the author’s breeding work with stone fruits are brought up to date. In addition to descriptive notes an alphabetical list is given of both the pure native plums and the new hybrid plums, showing the English meaning of the Indian names, pedigree, and year of introduction. Reference is also made to the work of improving native plums and sand cherries through selection.

Although sufficient time has not elapsed for a final report as to their relative value, the author gives as a guide to the fruit grower and nurseryman his estimate of the best varieties of each class of hybrids. These include varieties secured from the following crosses: Native plum × Chinese Apricot plum pollen, Japanese plum × De Soto plum pollen, and crosses of the western sand cherry with pollen of the Gold, Sultan, De Soto, Chinese Apricot, and Persian Purple-leaved plums.

Investigations on the mortality of plums, E. Rabaté (Prog. Agr. et Vit. (Ed. l’Est-Centre), 32 (1911), Nos. 53, pp. 197–202; 34, pp. 214–222).—An investigation into the cause of the rapid dying out of plum trees in certain plantations of Lot-et-Garonne, France, is reported. The author concludes that the rapid mortality of the trees is caused either by asphyxiation of the roots in soil saturated with stagnant water or through the underground action of root rot, or by a combination of these causes, the former being more prevalent. Methods of treating this trouble adapted to different soil conditions are suggested.

Results of experimental plantings with grapes grafted on American stocks at the Wädenswil Experiment Station, H. Schellenberg (Landw. Jahrb. Schweiz., 25 (1911), No. 4, pp. 277–288).—The data here presented indicate that with the judicious selection of American stocks no serious difficulty will be encountered in the reconstitution of the vineyards in German-Switzerland.

American grape stocks of the varieties selected for further trial by the Prussian experiment stations, F. Schmitthenner (Landw. Jahrb., 40 (1911), Ergänzungsb. 2, pp. 1–76, pls. 12, fig. 1).—Detailed descriptions are given of 18 grape stocks, including pure American species and America-American and Franco-American hybrids which are considered worthy of further trial in the reconstitution of German vineyards.

Report of the grape grafting station Geisenheim-Ebingen, Fischer et al. (Ber. K. Lehnanst. Wein. Obst u. Gartenbau Geisenheim, 1910, pp. 195–232, figs. 4).—This report embraces a record of the grafted varieties in the experiment station, observations on the various graft stocks employed, notes on hybrids, grafting experiments, etc.

In a preliminary experiment in the use of Nitragin in the nursery soils, Nitragin in combination with phosphoric acid and potash gave the best results, and Nitragin used alone gave better results than the check plat.

Report on the activities of the Royal American Grape Nursery in Asti for the period 1901 to 1910, G. Persi (Bol. Min. Agr., Indus. e Com. [Rome], 10 (1911). Scr. C, No. 8, pp. 13–32, figs. 3).—This consists of a review of operations conducted at the grape nursery established in Asti for the propagation, study, and dissemination of American vines. During the 10-year period under discussion over 2,000,000 grafted plants and over 200,000 cuttings consisting largely of Riparia and Rupestris, together with hybrids of these 2 species, have been distributed in various Provinces of Italy.

Report of the enological station of Haro for 1910, V. C. M. de Zúñiga (Estac. Enol. Haro Mem., 1910, pp. 151, pl. 1).—As in previous years (E. S. R.,
28, p. 540) this report summarizes the progress made in laboratory and field investigations, assistance rendered, etc.

The viticultural conditions in Algeria, J. WORTMANN (Landw. Jahrb., 40 (1911), Ergänzungsb. 2, pp. 77-98).—This comprises the results of an investigation of the grape industry in Algeria.

Storage test of shipping grapes, F. de CASTELLA (Jour. Dept. Agr. Victoria, 9 (1911), No. 8, pp. 531, 532).—A number of varieties of shipping grapes packed in cork dust and stored in the Victoria cool stores at a temperature between 33 and 34° F. were found to be in from fair to good condition at the end of 3 months.

Coffee culture; its future in the French colonies, A. JACOTOT (La Culture du Café, son Avenir dans les Colonies Françaises. Paris, 1910, pp. 191).—Part 1 of this work discusses the actual condition of production and consumption of coffee and the future of the coffee industry in the principal producing countries. Part 2 consists of a study of the actual conditions of the coffee industry in the various French colonies. It is concluded that the culture of coffee in conjunction with other products should be encouraged and that one of the best means to encourage the industry is to remove all taxes from coffee going from the colonies to the home country.

The pecan and hickory in Texas, E. J. KYLE (Texas Dept. Agr. Bul. 19, 1911, pp. 37, figs. 19).—A popular treatise on pecan growing in Texas, based on observations made and data collected over a number of years.

[Report on ornamentals], P. B. KENNEDY (Nevada Sta. Bul. 731, pp. 25-29).—Notes are given on the condition of a number of ornamental shrubs being tested at the station.

Chrysanthemums and how to grow them, I. L. POWELL (Garden City and New York, 1911, pp. 201, pls. 31).—A popular work containing directions for the culture and care of chrysanthemums grown for outdoor bloom and for cut flowers under glass.

FORESTRY.

Only 2.6 per cent of the hardy catalpa trees that were planted in 1908 were found to have a straight stem, late frosts having killed not only the terminal buds but the upper lateral buds as well. It appears probable that hardy catalpa will not prove successful in the upland region of Pennsylvania. The basket-willow experiments, which are being conducted in cooperation with the Forest Service of this Department, have shown so far that the varieties Welsh and Lemley are best suited for the severe climate in the vicinity of the station.

In the treatment of fence posts with creosote, the data given show that for chestnut posts a larger amount of creosote is absorbed by heating 4 hours than 3 hours when subsequently cooled for an equal length of time. After heating for a certain length of time in hot creosote, the length of time the posts are subsequently cooled in cold creosote affects the amount of creosote absorbed. Posts cooled 4 1/2 hours absorbed 0.8 lb. of creosote and posts cooled 12 hours absorbed 1.4 lbs. Oak posts of 3 varieties absorbed an average of 1.2 lbs. of creosote and the cost of treatment was 3.3 cts. Posts of Pennsylvania pitch pine absorbed 6.97 lbs. of creosote, thus raising the cost per post to 16.5 cts.
The results show that for each species of wood a formula should be determined which will show the length of time the posts should be heated in hot creosote and cooled in cold creosote to obtain the degree of penetration desired.

Preliminary report on forestry investigation at Colesborne, Gloucestershire, H. A. Pritchard, R. G. Stapleton, and M. Kershaw (Ann. Sci. Bul. Roy. Agr. Col. Cirencester, 1910, No. 2, pp. 47-58, pls. 3, fig. 1).—The investigation in question is being conducted by the Royal Agricultural College, Cirencester, to determine the causes of the extreme differences in the development of different species and even in the same species in a plantation on thin, poor, calcareous soils. The plantation is described and the experiments being conducted are outlined. They are to include studies of the action of various conditions of soil and climate, as well as such indirect agencies as aspect and contour on tree development.

Annual progress report on forest administration in the lower Provinces of Bengal for the year 1908-9, G. S. Hart (Ann. Rpt. Forest Admin. Lower Prov. Bengal, 1908-9, pp. 11+50+3, map I).—Customary report relative to the constitution, management, silviculture, and exploitation of the state forests in the lower Provinces of Bengal, including a financial statement for the year. The more important data are appended in tabular form.

The forest re-formation and private ownership: A historical study, comparative law, new projects, L. Ducrot (La Réforme Forestière et la Propriété Privee. Étude Historique-Droit Comparé, Projets Nouveaux, Lyon, 1910, pp. 171+333).—In view of the growing interest relative to the administration, conservation, and extension of forest lands, the author has aimed to bring together the important literature on the subject having special bearing on French conditions.

Part 1 contains a historical sketch and analysis of French legislation from ancient times up to the present in its relation to private ownership. Part 2 contains a critical study of the forest laws of Italy. In part 3 the question of forest re-formation is presented, both from the standpoint of the Government and of the private individual, including various projects proposed for solving this question.

A bibliography on the subject is included.

Example of a German working plan, trans. by A. B. Recknagel (Forestry Quart., 9 (1911), No. 3, pp. 391-399).—This comprises a summary of the methods of management which form a part of the Working Plan for the Tegernsee Forest in Bavaria, the manuscript of which is in possession of the Yale Forest School. The plan deals with a practically virgin forest of spruce with fir and beech in mixture, and it is suggested that it will be particularly applicable to similar conditions in America.

The need of a vigorous policy of encouraging cutting on the National Forests of the Pacific coast, B. P. Kirkland (Forestry Quart., 9 (1911), No. 3, pp. 375-390).—After analyzing the conditions and factors involved in the development of methods of cutting and regeneration in the National Forests of the Pacific coast, the author concludes in part that present cutting based on a sustained annual yield can, without any damage to the future, yield liberal revenues to federal and state governments and that all possible present revenue within a sustained annual yield basis, which is not taken, will be irrevocably lost. The forests, it appears, are covered for the most part with
overmaturity stands in which the loss by decay offsets all growth. Clear-cutting methods must be practiced and artificial regeneration will be cheaper and probably better than natural regeneration from scattered seed trees.

A method of assessing fire damages in the Southwest, R. Rogers and B. Moore (Forestry Quart., 9 (1911), No. 3, pp. 412-419).—This consists of a detailed statement of a suggested method for finding the value of forest products destroyed by fire in the Southwest.

The Biltmore stick and its use on National Forests, A. G. Jackson (Forestry Quart., 9 (1911), No. 3, pp. 406-411, fig. 1).—The author has derived and here presents a formula which may be used for constructing an accurate scale on the Biltmore stick, an instrument which has recently been used to some extent in place of calipers or diameter tape in measuring diameters of large trees. Comparative measurements made with all of the above instruments indicate that the Biltmore stick has a practical value as a field instrument.

The climatic and hygienic influences of forest growth, J. M. Anders (Med. Rec. [N. Y.], 80 (1911), No. 14, pp. 659-661).—A paper on this subject read before the American Climatological Association, Montreal, 1911.

Experiments on ramming forest trees, H. A. Pritchard (Ann. Sci. Bul. Roy. Agr. Col. Cirencester, 1910, No. 2, pp. 89-93, pl. 1).—In 1909 a small number of trees of several species was planted at the college to ascertain whether the results obtained by Pickering in ramming fruit trees (E. S. R., 20, p. 1034) will be borne out in the case of forest trees. Four-year-old trees were used.

During the 2 years the trees were in the ground it was quite impossible to detect the rammed trees from those that were not rammed. The trees were then carefully lifted out and studied. The results appear to show that extreme care in digging holes and carefully spreading out the roots is not so important as packing the soil about the roots when the trees are planted. Except possibly for larger trees than are usually planted out for silvicultural purposes, however, the results did not seem to furnish any justification for the practice of ramming, provided that the soil about each tree is firmly trod upon after planting. The tests are being conducted on a larger scale.

Some useful woods of Kamerun.—II. Leguminosae, H. Harms (Notizbl. K. Bot. Gartens u. Mus. Berlin, 1911, App. 21, No. 2, pp. 9-75, figs. 23).—The author has brought together the important information relative to a large number of timber trees of Kamerun belonging to the Leguminosae. Under each species consideration is given to its botanical characteristics, anatomy of the wood, distribution, native uses, and importance to European wood industries.

Utilization of osage orange, H. Maxwell ([1911], pp. 14).—This pamphlet embraces the results of an investigation of the utilization of the osage orange, conducted cooperatively by the Forest Service of this Department and the farm wagon department of the National Implement and Vehicle Association. Data are given on the utilization of this wood for wagon parts, fence posts, bridge piling, house blocks, telephone poles, and miscellaneous products. Consideration is also given to the future supply of osage orange.

Although the natural range of osage orange covers about 10,000 square miles, the stands have been so greatly reduced that commercially the wood is now found in restricted patches and strips which grouped together would not exceed 400 square miles. It is concluded that a drain much smaller than the present annual cut of 26,000,000 ft. b. m. will speedily deforest the remaining areas. It is expected, however, that the rate of cutting will decline as scarcity increases.

The commercial mahoganies, P. Busch (Tropenpflanzer, 15 (1911), No. 9, pp. 479-493).—Descriptive notes are given of the commercial mahoganies, which
are treated with reference to both their producing countries and their botanical
classification.

Eucalyptus culture in Hawaii, L. Margolin (Bd. Comrs. Agr. and Forestry
Hawaii, Div. Forestry Bul. 1, 1911, pp. 80, pls. 12).—This embraces the results
of a study of eucalyptus plantations in Hawaii, conducted cooperatively by
the Forest Service of this Department and the Territorial Board of Agriculture
and Forestry. The object of the report is to put before landowners in Hawaii
comprehensive suggestions and definite recommendations in regard to growing
and managing eucalyptus forests.

The important phases discussed include physical requirements, habit of
growth, enemies, uses of eucalypts, establishment, care, and management of
eucalypts, growth, yield, and financial returns, and forest management for
sugar plantations.

An appendix contains notes on the character and uses of various species of
eucalypts in Australia, classification of species by size, lists of eucalypts
planted in Hawaii, a bibliography on eucalypts, and field notes on the trees
found planted in Hawaii.

A manual for eucalyptus planters, E. Navarro de Andrade (Manual do
Plantador de Eucalyptos. Sao Paulo, 1911, pp. VI+323, figs. 183).—Part 1 of
this manual, which has special reference to the culture of eucalypts in Brazil,
treats of the climatic and soil requirements of eucalypts, methods of reproduc-
tion, planting operations, culture and management of eucalyptus stands, protec-
tion from insects and other enemies, cost, yields, returns, etc., timber and other
products, and methods of regeneration. Part 2 takes up the various species of
eucalypts relative to their botany, distribution, products, and behavior under
cultivation.

Guayule (Parthenium argentatum): A rubber plant of the Chihuahuan
Desert, F. E. Lloyd (Carnegie Inst. Washington Pub. 139, 1911, pp. VIII+213,
pls. 46, figs. 20).—This work embraces the results of investigations conducted
with guayule by the author for a number of years with the view of developing
a successful method for growing this desert rubber plant. Introductory re-
marks deal with the discovery of guayule, the development of the rubber
industry, and cultural attempts. In the succeeding chapters guayule is dis-
cussed in detail relative to its environment, morphology, reproduction, anatomy
and histology, the resin canals, the origin and occurrence of rubber, vegetative
reproduction, and conclusions relative to the methods of growing and pos-
sibilities of guayule under forestal or under cultural treatments.

A bibliography is appended.

Treatment of shingles with creosote to increase their durability, J. A.
Ferguson (Pennsylvania Sta. Rpt. 1910, pp. 308-310, pl. 1).—An account is
given of experiments conducted during the past year to determine the practic-
cability of utilizing for shingles inferior and perishable woods treated with
creosote, and to determine the amount of creosote absorbed by a bundle of
shingles.

The shingles chosen for the experiment were of loblolly pine, Pennsylvania
pitch pine, and chestnut. They were treated by the open-tank process. The
chestnut shingles absorbed 17.1 lbs. of creosote per bundle at a cost of 45.5 cts.
Pennsylvania pitch pine absorbed 15.5 lbs. of creosote per bundle at a cost of
41.7 cts., and loblolly pine shingles 11.3 lbs. of creosote per bundle at a cost of
32.5 cts. These shingles, together with western cedar, redwood, and untreated
chestnut shingles, are to be tested for durability over a term of years.
Notes on plant diseases occurring in North Carolina, F. L. Stevens and J. G. Hall (North Carolina Sta. Rpt. 1910, pp. 59-72, figs. 5).—Notes are given on a number of plant diseases reported from different parts of North Carolina, most of them being on fruit, field, and garden crops.

Plant diseases in Virginia in the years 1909 and 1910, H. S. Reed and J. S. Cooley (Virginia Sta. Rpts. 1909-10, pp. 99-119, figs. 13).—The results of a plant disease survey of the State are given, based upon replies to circulars sent out to about 900 addresses, as well as on the personal observations of the authors. The diseases are grouped according to the host plants, and some notes are included on the relative distribution and damage. In some instances suggestions are given for control.

Investigations on the diseases of beets.—5, On the causes of the damping-off disease of beet seedlings, L. Peters (Arb. K. Biol. Anst. Land u. Forstw., 8 (1911), No. 2, pp. 211-259, figs. 12).—The author discusses the life cycles of, and the various parts of the beet seedlings which are attacked by, the 3 main fungi responsible for the damping-off disease, viz. *Pythium debaryanum*, *Phoma beta*, and *Aphanomyces laevis*.

It was found that *P. debaryanum* not only attacks and kills the hypocotyl and upper parts of the roots, but may also cause the death of the main root of young plants and of the side rootlets during the entire vegetative period. *P. beta* as a damping-off fungus destroys the lower parts of the hypocotyls and the upper parts of the roots, but does not attack the main root tip or side roots. *A. laevis* attacks the plants very much like *P. debaryanum*, causing the death of the seedlings.

Investigations on the diseases of beets.—6, On the occurrence of the damping-off organisms in the soil, W. Russe, L. Peters, and P. Ulrich (Arb. K. Biol. Anst. Land u. Forstw., 8 (1911), No. 2, pp. 260-302).—It is claimed that the damping-off disease of sugar beets can occur through organisms which are present in the soil or on the seed when planted. These soil organisms are able to kill the germinating seed and thus materially reduce the stand. The mechanical, physical, and chemical condition of the soil will also influence the stand without the intervention of any organism.

The greater part of the damping off results from the attacks of *Phoma beta*, as this organism is generally present on the seed in large numbers. *Pythium debaryanum* attacks the beet plants immediately after germination and in the earlier developmental stages, while *Phoma beta* and *Aphanomyces laevis* attack the plants somewhat later. Damp weather favors *Pythium* and *Aphanomyces*, while *Phoma* is more of a dry weather organism. The damping-off disease is especially bad on certain types of soil, viz. heavy encrusting soils, low soils rich in humus, moor soils, limy sands, and sandy soils.

Cabbage club root in Virginia, H. S. Reed (Virginia Sta. Bul. 191, pp. 12, figs. 5).—An account is given of the occurrence of cabbage club root (*Plasmodiophora brassicae*) in Virginia, together with observations on the spread of the disease by cultivators, the feet of horses, soil erosion, and through feeding of diseased cabbage to stock. Experiments are also reported on the control of the disease which were begun in 1909 and carried on for 2 years. The experiments consisted of soil treatments with lime, acid phosphate, and stable manure, comparisons being made of the yield of cabbage from the different plots. The
usual custom of planting the seed in a hill and subsequently thinning to one plant was followed in order to prevent the introduction of diseases from the seed bed.

As a result of the experiments it appears that the use of lime is distinctly beneficial in combating club root disease in the field, but that acid phosphate is of little effect. Stable manure brings about conditions that are decidedly favorable for the spread of the disease.

The author recommends for the control of club root special effort to prevent the introduction of the disease into noninfected fields; the practice of crop rotations which will allow at least 3 years between crops of cabbage, rutabagas, or turnips; and limiting the application of stable manure or acid phosphate to the crop which precedes cabbage. Lime should be applied at the rate of 100 bu. or more per acre 1 or 2 years before planting the cabbage.

On the curly leaf disease of cotton, G. Kränzlin (Pflanzer, 7 (1911), No 6, pp. 327-329, pls. 4).—The author reports the results of further investigations on this subject (E. S. R., 25, p. 652), in which experiments on the cause of the curly leaf of cotton indicate that the disease is caused by leaf hoppers (cicads).

A serious lettuce disease, F. L. Stevens (North Carolina Sta. Bul. 217, pp. 21, figs. 8).—Continuing work previously noted (E. S. R., 25, p. 548), the author describes a disease of lettuce due to Sclerotinia libertiana, which is known to occur over a considerable portion of the eastern part of the United States. In some regions it has been reported as being severely epidemic, losses of from 10 to 70 per cent being reported in various parts of North Carolina.

The disease is said to appear sometimes the first season the crop is grown in a given soil, but usually not until several crops have been raised. A study of the fungus showed that the spores are comparatively short-lived. The sclerotia are long-lived and are the only resting stage adapted to perpetuate the fungus.

Various methods of control have been tested. These include soil disinfection by heat or by chemical solutions, mulching, etc., but in the experiments conducted by the author in commercial beds none seemed very satisfactory. An experiment was then undertaken in which lettuce beds were thoroughly inoculated with sclerotia and seeded to lettuce. The beds were examined and as soon as a diseased plant appeared it was removed and the ground about it drenched with Bordeaux mixture or a solution of copper sulphate.

As a result of his investigations the author thinks that the disease may be controlled by a careful inspection of lettuce beds every other day and pulling up and burning all diseased plants. The place in the bed from which the plants are removed should be drenched with Bordeaux mixture or sulphate of copper solution, and the inspection continued throughout the season. The next year the same treatment should be followed, and it is thought probable that two years of this treatment will almost, if not entirely, eradicate the disease.

Heterosporium variabile, its relation to Spinacia oleracea and environmental factors, H. S. Reed and J. S. Cooley (Virginia Sta. Rpts. 1909-10, pp. 78-99, figs. 16).—This is a detailed account of investigations a preliminary note on which has been given elsewhere (E. S. R., 23, p. 350).

The authors, summarizing their investigations, state that the disease of spinach popularly known as rust is caused by the fungus H. variabile, and their investigations show that it is a weak parasite and usually infects spinach plants that have been injured or weakened by other agents. Peronospora effusa, a parasite of the spinach, appears to be a forerunner of the rust, and winter injury is another predisposing factor to the appearance of Heterosporium. Considerable variability in the form and habit of the fungus is noted, and in cultures it first grows poorly as a saprophyte and afterwards, changing its form and habit, grows luxuriantly.
The character of spore formation, growth of the mycelium, etc., are described at some length.

**The diseases of sugar cane.** C. MauBlanc (Agr. Prat. Pays Chauds, 10 (1916), Nos. 88, pp. 43-56, fig. 1; 89, pp. 143-148, fig. 1; 90, pp. 232-252, figs. 4; 91, pp. 312-320, fig. 1; 92, pp. 379-400, figs. 4; 93, pp. 502-506, fig. 1).—This is a discussion of the common diseases of sugar cane, based on the notes of G. Delacroix, which includes both nonparasitic and parasitic forms and gives the symptoms, causes, and methods of combating each disease when known.

The following diseases and parasites are noted: Dichotomy of the stem, malformation of the internodes, abnormal arrangement of the buds, panachure, chlorosis, torsion of the leaves, “disease of Dongellian,” changes produced by injurious substances in the soil, alterations produced by poisons, gymmosis, smut (Ustilago sacchari), rind disease (Colletotrichum falcatum), pineapple disease (Thielaviopsis paradoxa), Coniothyrium sacchari, Lastodioides theobromae, root rot (Marasmius sacchari), cane rot (Schizophyllum commune and Trametes pasilla), Spheronema adiposum, Cytopora sacchari, Saccharomyces apiculatus sacchari, bacterial gummosis, point rot, collar rot, sereh (a disease characterized by shortened internodes which crowd the leaves together and cause the young blades at the top to open sooner than on normal plants and to spread out fan-like), leaf-splitting disease, root diseases (Ithyphallus ciclicoides and I. coralloides), Pythium, nematodes, Suntalum album, Alecra basilicinosis, rust (Uromyces kühnii), leaf spot (Cercospora köpkei, C. sacchari, and C. longipes), red spot of the sheaths (C. vaginae), black spot (C. accesosum), ring disease (Leptosphaeria sacchari), Venturia sacchari, Sphaerella striiformans, Phylobachura sp., Pestalozzia sp., Sclerotina of the leaves, sheath rot (Sclerotium spp.), and sooty mold.

**The sereh disease of the sugar cane** (Agr. News [Barbados], 10 (1911), No. 241, pp. 238, 239).—The symptoms and characteristics of this disease are given, together with a discussion of its probable cause. It is claimed that no known organism has as yet been shown to be the cause of this disease.

**Tomatoes and Irish blight.** D. McAlpine (Jour. Dept. Agr. Victoria, 9 (1911), No. 6, pp. 379-382, fig. 1).—Attention is called to the infection of tomatoes, especially of the fruits, by the late blight from adjacent diseased potato plants. The results are also given of cross inoculation experiments on both the tomato and potato with the spores of this fungus.

It was found that tomatoes and potatoes are mutually infected, and that even with the tough skin unbroken, spores falling on them when moist can cause infection, producing a fresh crop of spores within 9 days.

**Some frost injuries of fruit trees,** G. Lüstner (Deut. Obstbau Ztg., 1911, No. 14, pp. 233-236, figs. 5).—Descriptions are given of frost injuries to the leaves of apples, pears, and raspberries, due to late freezes in which the temperature fell from 2 to 6° below the freezing point during the month of April.

**A new disease of apples,** J. P. Stewart (Pennsylvania Sta. Rpt. 1910, pp. 267, 268, pl. 1).—A description is given of a new disease of apples, which is apparently due to physiological disturbances, its most conspicuous characters being shown in the twigs of the current season’s growth. These twigs lose their normal color and become dull, blistered, and mottled, and at a casual glance the effect somewhat resembles that produced by the San José scale. Immediately under the epidermis of the diseased areas and extending about halfway to the cambium may be seen numerous small brown spots where the tissues are dead or dying. Later, on the surface, the epidermis cracks around and over the diseased spots, and they become rough, scablike, and slightly sunken through the drying out and death of the tissues beneath. In some cases the cracks go deeper and involve the wood. The leaves are affected sooner or later, probably
through the girdling of the twigs. They turn brown, dry out, and crumble, beginning at the tips and outer margins.

The disease, it is said, usually becomes well developed and conspicuous by the middle or latter part of August. Specimens of diseased material were submitted to pathologists who failed to identify it with any known disease, and this is believed to be the first record of its occurrence on apple trees in this country. There seems to be some evidence which suggests a connection between the disease and heavy applications of certain fertilizers, and experiments are in progress to determine this point.

Hold-over blight in the pear, W. G. Sackett (Colorado Sta. Bul. 177, pp. 2-8, figs. 2).—On account of difference of opinion among fruit growers as to whether the micro-organisms which produce fire blight in the pear, apple, quince, and apricot can live over winter in diseased limbs, twigs, and fruit under Colorado conditions, an investigation was begun in 1909 and carried on through the winters of 1910 and 1911 to determine whether in addition to occurring in the cankers the organism remains viable over winter in infected twigs.

Material was collected from widely separated regions, representing a considerable portion of the orchard district of Colorado, and examined during the winter or early spring, cultures grown, and inoculations made into young pear seedlings. Out of a total of 83 twigs examined, 21 contained living *Bacillus amylophilus*, indicating that the organism is carried over in twigs and small limbs from one season to the other.

As having an important bearing on the control of this disease, the author quotes from an unpublished experiment of H. R. Fulton, botanist of the Pennsylvania Experiment Station, which seems to indicate that the bacteria of fire blight do not remain viable in twigs that have been cut and allowed to dry upon the ground. Out of 35 twigs containing the organism when cut, at the end of a week only 4 contained viable bacteria, and most of these had become inactive after 3 to 5 days.

It is believed from the comparatively rapid death of bacteria in cut twigs left upon the ground that there is no necessity for rigid destruction of cut-off twigs, as has been previously recommended. Further observations, however, will be made on this subject before definite conclusions are warranted.

Withertip, R. E. Smith (Col. Cult., 37 (1911), No. 4, pp. 76, 77).—It is claimed by the author from his investigations and from tests made under his supervision that the withertip fungus is absolutely not a parasite on healthy citrus trees or fruit in California, but that it may occur on diseased or much weakened trees, on trees which have received any injury or sudden shock (such as might produce gum disease, dropping of the leaves, die back, or any other diseased condition), on branches or leaves injured by fire, fumigation, or frost, on the leaves, blossoms, or fruit when removed from the tree and partially dead, on fruit weakened by too low a temperature in cold storage, and, in short, on any citrus tissue which is dead or nearly so.

A contribution to the life history, parasitism, and biology of Botryosphaeria ribis, J. G. Grossenbacher and B. M. Duggar (New York State Sta. Tech. Bul. 18, pp. 113-190, pls. 12, fig. 1).—The results are given of a study of the fungus *B. ribis*, which produces a destructive blight or wilt of currants.

This disease was first noticed by D. G. Fairchild (E. S. R., 8, p. 53) and was ascribed to a sterile fungus. Later on the disease was studied by Durand and reported as due to *Nectria cinabaria* (E. S. R., 9, p. 359). As a result of later work, begun by the second author of the bulletin and continued and completed by Mr. Grossenbacher, it was definitely determined that the disease is
due to *B. ribis*, and its life history and some of the more important points in its biology have been worked out.

The fungus infects and kills young currant shoots about the time they have completed their elongation growth, and it may cause older branches and parts of bushes to wilt throughout the summer, due to the advance of the fungus from the shoots infected during former seasons.

As noted above, the disease was first considered due to a sterile fungus, no spores having been observed on currant bushes or in pure cultures, and the authors find that there is no spore formation present when a branch wilts except occasionally at the point where the parasite enters. The investigations showed, however, that 3 types of spores are developed on the host, although the fungus usually remains sterile in pure cultures. Several fungi may appear saprophytically on the dead bushes, and one of the most prevalent, *N. cinnabarina*, has been considered the cause of the disease.

As the study of the life history of the fungus shows that the spores are produced on dead stems and branches of the host and that the currants are most commonly infected in midsummer, it is believed probable that the disease may be checked or reduced by carefully pruning blighted plants during May, instead of practicing winter pruning, as is at present customary. All prunings should be burned instead of allowing them to lie upon the ground during the summer.

A fungus disease of *Ribes aureum*, RÖTGER (Dent. Obstbau Ztg., 1911, No. 14, pp. 236, 237).—Attention is called to a disease of this currant, due, it is claimed, to *Camarosporium ribis*, which produces circular spots on the epidermis of young, nonwoody twigs.

On a disease of *Ribes* species due to *Botrytis cinerea*, F. KRAUSE (Dent. Obstbau Ztg., 1911, No. 14, pp. 237—239, figs. 3).—The author holds that the cause of the disease of *R. aureum* noted above, as well as of other species and crosses of *Ribes*, is due to *B. cinerea*, as the sclerotia of this fungus was obtained from the diseased bark and also from the pith of the attacked stems.

The ascogenous form of the fungus causing dead-arm of the grape, C. L. SHEAR (Phytopathology, 1 (1911), No. 4, pp. 116—119, figs. 5).—The author reports the finding of an ascogenous form associated with the pycnidia of *Fusicoccum viticolum*, which is believed to be the perfect stage of this fungus.

Cultures from ascospores of this pyrenomycete, which is apparently a species of Cryptosporia, produced pycnospores and scolecospores practically identical with those produced from the pycnospores of *F. viticolum* taken from grapevines diseased with dead-arm. The fungus is tentatively called *Cryptosporiella viticola* n. sp. and a description is appended.

Chlorosis and mildew, G. PROVOST-DUMARCIAIS (Jour. Agr. Prat., n. ser., 22 (1911), No. 28, pp. 43, 44).—It is claimed that the unusual wet season of 1910 caused an abnormal amount of lime to be present in the soil water. On being absorbed by the grape roots this produced a diseased or weakened condition of the vines, thereby making them more susceptible to the attacks of the mildew.

[Double flower in dewberries and blackberries] (North Carolina Sta. Rpt. 1910, pp. 10, 11).—A brief account is given of investigations on the double flower of dewberries and blackberries, the cause of which is due apparently to the presence of a fungus in the flower bud. The relative resistance of different varieties is being studied, and some work is in progress on other methods of control.

A new raspberry disease, H. ROSENTHAL (Dent. Obstbau Ztg., 1911, No. 14, pp. 239, 240, figs. 2).—Attention is called to a disease of raspberries which attacks the young shoots in the early summer, producing brown spots on them and causing them to become long, slender, and almost leafless. The cause of this disease is not given, but it is supposed to be due to the attack of a fungus.
The hollyhock rust, its nature and developmental phases, J. Eriksson (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 25, pp. 1776-1779).—The author gives the results of a 2-year biological study of this rust (Puccinia malvacearum). Two common hosts were found, viz, Althaea rosea and Malva silvestris, but many other species of the Malvaceae are also attacked by the rust.

It is claimed that the dissemination of this rust from one locality to another is through diseased seeds or diseased rootstocks. At first, that is during the first 3 months, all the stalks remain unaffected, and they will continue so if the seeds from which they came were healthy, but if the seeds were from diseased plants the rust will suddenly appear vigorous and fully developed on the leaves. This first appearance is called the primary eruption, and differs from the latter and more irregular pustules which successively appear on all parts of the plant, called the secondary eruption of the rust. The primary outbreak originates from the interior of the host, while the secondary infection is produced from the sporiola of the primary sori.

The rust winters over in the rootstocks of A. rosca in the form of mycoplasma which enters into a kind of symbiosis with the living cells of the host, and in the early spring gives rise to the primary infection. In the autumn the sori produce 2 forms of spores similar morphologically, but germinating differently. The greater part of these spores germination form short, thick promycelia which produce sporidia. The other type of spores on germination form long filaments or hyphae, slender and straight, terminating in very short joints which fall off as conidia. The usual type of sporidia on germination forms a vesicular filament which penetrates into the palisade cells and in 10 to 20 days produces new sori.

The conidia on germination empty their contents as a plasmic mass on the epidermis of the leaf, and penetrating into the cells of the epidermis pass from there into the neighboring cellular tissues, where they take on a mycoplastic life. After this no evidence of rust infection is seen, but the infected leaves grow vigorously and seem perfectly healthy. In the embryo of the seed obtained from diseased plants there is no trace of mycelium, and yet it is from these seed that the diseased plants are developed.

On the artificial production of the black canker of the chestnut, G. Brioni and R. Farneti (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 20 (1911) I, No. 9, pp. 628-633).—The authors claim to have produced all the symptoms of black canker by inoculating the living bark of the chestnut with the spores of Coryneum perniciosum, and also with the ascospores of its perfect stage (Melanconis perniciosus).

**ECONOMIC ZOOLOGY—ENTOMOLOGY.**

Revision of the spiny pocket mice (genera Heteromys and Liomys), E. A. Goldman (U. S. Dept. Agr., Bur. Biol. Survey. North American Fauna No. 34, pp. 69, plis. 3, figs. 6).—The spiny pocket mice, although of small size, are of considerable economic importance owing to the fact that they feed chiefly on seeds, including weed seeds, corn, wheat, and beans. They are widely distributed in the drier parts of North America. "While apparently not so injurious to crops as some other rodents, these mice, in some places, are among the most
numerous of the small mammals, and their food habits, as well as those of the great family to which they belong, should be better known."

"Like many other small rodents, they are nocturnal and so shy that their presence in large numbers is readily overlooked. They inhabit widely differing faunal areas, but everywhere burrow in the ground under bushes, trees, rocks, logs, or other shelter, and generally are most numerous in such cover along the borders of fields. The entrances to the burrows are inconspicuous, opening, as they commonly do, under thick beds of leaves, logs, or rocks; small quantities of earth are thrown out about them from time to time, but not usually forming a definite mound. These pocket mice reach their greatest abundance in semi-arid, partially wooded regions, both plains and mountain slopes being well populated with them. Some species of Heteromys, however, inhabit humid heavily forested areas apparently throughout middle America. From 3 to 5 young are produced at a birth, 4 being the usual number. While the young seem more numerous in spring and early summer than at other times, it is evident that the animals breed throughout the year."

Thirteen species and 1 subspecies of Heteromys and 10 species and 18 subspecies of Liomys are recognized by the author, of which 1 species (temporalis) of Heteromys and 1 species (guerrerensis) and a subspecies (irroratus pretiosus) of Liomys, all 3 from Mexico, are characterized for the first time.

**Distribution of the American egrets, W. W. Cooke** (U. S. Dept. Agr., Bur. Biol. Survey Circ, 34, pp. 5, maps 2).—A brief discussion is given of the 2 common white herons or egrets (Herodias egretta and Egretta candidissima), together with maps which show their original range.

It is stated that the demand of the millinery trade for plumes has caused such a wholesale slaughter of these 2 species that they are almost extinct over large areas where they were formerly common. Fortunately in the case of both of these species breeding colonies still remain in the southern part of the United States to serve as centers of distribution to the districts formerly included in the range.

**Eighth annual report of the state entomologist of Montana, R. A. Cooley** (Montana Sta. Bul. 82, pp. 137-144).—This report consists of a brief discussion of the work of the entomological department. It calls attention to the farmers' and fruit growers' need for more information, mentions the need of a movable exhibit, and discusses the relation of the state entomologist's office to other organizations in the State, the prices of insecticides in Montana, the necessity for a Montana law regarding adulterated insecticides, etc.

**Department of entomology, S. B. Doten** (Nevada Sta. Bul. 734, pp. 40-46).—This report consists of brief accounts of an open-air insectary which has given very successful results, photographic records, and the more important insects of the year, namely, San José scale, oyster shell bark louse, European elm scale, codling moth, ants, cutworms, and Mediterranean flour moth. It is stated that the alfalfa leaf weevil had not been found in Nevada at the time of writing.

**Report of the entomologist, R. I. Smith** (North Carolina Sta. Rpt. 1910, pp. 31-33).—This report consists largely of brief statements of the occurrence during the year of the lesser corn stalk borer (Elasmopalpus lignosellus), catalpa sphinx (Ceratomia catalpa), the sugar-cane borer or larger corn stalk borer, woolly apple aphis, striped flea beetle (Phyllostreta vittata), cross-striped cabbage worm (Evergestis rimosalis), Hessian fly, and strawberry weevil.

**Report on economic entomology and zoology, F. V. Theobald** (Jour. Southeast Agr. Col. Wyc, 1910, No. 19, pp. 83-211, pls. 56, figs. 8).—This is the author's annual report on the occurrence of injurious insects, etc., in England. They are considered under the headings of animals injurious to man's domesticated
animals, fruit trees and bushes, corn crops, root crops, pulse, hops, vegetables, and flowers, those causing annoyance to man, and those injurious to buildings, furniture, stores, and food. An account of the life history of the pear thrips, *Euthrips pyri*, in England as followed by the author is included.

Hosts of insect egg parasites in North and South America, II, A. A. Girault (Psyche, 18 (1911). No. 4, pp. 156-153).—This is in continuation of the paper previously noted (E. S. R., 19, p. 55).

**[Mexican insect pests]** (Estac. Agr. Cent. [Mexico], 1909, Circ. 12, pp. 2, pl. 1; 1910, Circs. 22, pp. 9, pls. 6; 26, pp. 8, pls. 4; 33, pp. 11, pl. 1).—These circulars are devoted to the fruit flies, ticks, ectoparasites of fowls, and the bean conchuela (*Eptithona cornuta*), and are by R. Ramirez, G. Gandara, A. Madariaga, and J. R. Inda, respectively.

Friendly insects, W. W. Froggatt (Dept. Agr. N. S. Wales, Farmers' Bul. 34, 1910, pp. 18, pls. 4, figs. 15).—This is a popular account of the parasitic and predaceous insects of Australia.

A contribution to the study of insects injurious to cotton in the Transcaspian District, R. Uvarov (Russ. Ent. Obzor., 11 (1911), No. 1, pp. 28-37).—This article treats briefly of the various insect pests of cotton in the Transcaspian District.

The cacao thrips (*Heliothrips rubrocinctus*), F. W. Urich (Dept. Agr. Trinidad Bul., 10 (1911), No. 67, pp. 66-73; reprint, pp. 10, pls. 3).—This summarized account of *H. rubrocinctus* includes a description of its several stages. The cashew tree is said to be one of the favorite food plants of this species, the author being led to think that it may be the original one. In some localities certain cashew trees lose their leaves regularly through its attack. The author has also observed thrips on guava, roses, almond (*Terminalia catappa*), and mango, as well as cacao.

Two new capsid bugs, resembling the tea mosquito bug, found attacking bamboos on gardens in Cachar, C. B. Antram (Indian Tea Assoc., Sci. Dept. Quart. Jour., 1911, No. 2, pp. 1-3, pls. 2).—A brief account of *Mythoillus manni* and *M. antrami*.

Results obtained in the study of the froghopper during the wet season of 1910, L. H. Gough (Dept. Agr. Trinidad Bul., 10 (1911), No. 67, pp. 5-50, pls. 7, fig. 1).—The author here reports studies conducted, under the headings of (1) history of the froghopper blight in Trinidad, compiled from published records: (2) the symptoms and results of the blight; (3) life history of the froghopper, including its geographical distribution; and (4) methods of prevention of the damage caused.

On some Coccidæ affecting rubber trees in Ceylon, with descriptions of new species, E. E. Green (Jour. Econ. Biol., 6 (1911), No. 2, pp. 27-37, pls. 2).—Four species affecting rubber trees are described as new, namely, *Inglesia castillioae*, *Mytilaspis fasciata*, *Tochardia albizzic*: and *Dactylionis crotonis*.

Spraying for the melon aphid, M. H. Swenk (Nebraska Sta. Rpt. 1910, pp. 35-57, figs. 5).—Following a brief account of the life history, habits, and injury of this species, spraying experiments are reported. Lady beetles and their larvae are thought to be the most valuable and effective of the natural enemies, especially *Hippodamia convergens*. The larva of *Allograpta obliqua* is the most abundant and useful of the 4 species of syrphus flies, and the larvae of *Chrysopa oculata*, *C. nigricornis*, and probably other species are important enemies of the pest.

In experiments conducted with kerosene emulsion, it was found that in order to destroy the aphids it must be used at a strength that would burn the tender leaves. Experiments were then made with 5 other washes, namely,
soap-and-tobacco wash, resin soda fish-oil wash, soap and fish-oil wash, resin soda wash, and tobacco decoction wash. The soap-and-tobacco wash, consisting of 2½ lbs. of soap dissolved in a gallon of water, mixed with 1 qt. of strong tobacco decoction and boiled 5 minutes, then diluted to make 5 gal. gave the best results, the aphids being practically all killed while the plants were not seriously injured by the spray. The resin soda fish-oil wash also killed the aphids, but the plants were somewhat more injured. The soap and fish-oil wash burned the foliage so badly that it was at once discarded, while the resin soda wash and the tobacco decoction used were ineffective. From further experiments conducted with soap-and-tobacco washes, the author concludes that ordinarily prepared tobacco decoction alone is not satisfactorily effective, but that when combined with soap suids it does the work well. A wash made up of 1½ lbs. of soap dissolved in ½ gal. of water with ½ gal. of strong tobacco decoction added and diluted to make 5 gal. will prove an effective wash in controlling the melon aphid and will not injure to any serious extent the foliage of either muskmelons or cucumbers.

The commercial tobacco extract "Blackleaf," which contains 2.7 per cent of nicotin, was tested at 3 strengths, namely 1:25, 1:50, and 1:70. "The results seem to indicate that the 1:50 dilution was sufficiently more effective than the 1:70 wash to justify the use of the greater strength. The 1:25 dilution, while not injurious to the plants, was unnecessarily strong and therefore not economical." After comparing the cost of the various soap-and-tobacco washes the author concludes that Blackleaf is the cheapest effective spraying material tried, while it also has the advantage of being practically ready for use, is of uniform and definite strength, and somewhat easier of application because of its greater thinness.

Attention is called to the importance of gathering together and burning the vines as soon as the crop is gathered and in this way destroying the aphids which are harboring thereon.

The large moth borer of sugar cane (Castnia licus), F. A. Stockdale (Proc. Agr. Soc. Trinidad and Tobago, 19 (1910), No. 4, pp. 114-129).—An account of the life history, habits, and remedial measures for this insect.

An insect pest of pigeon peas, F. A. Stockdale (Journ. Bd. Agr. Brit. Guiana, 4 (1911), No. 4, p. 239).—The larvae of the skipper butterfly Eudamus proteus are said to be very destructive to young pigeon-pea plants (Cajanus indicus) in the Pomeroon District of British Guiana.

Combating cotton worms, G. Gandara (Estac. Agr. Cent. [Mexico], Bol. §3, 1910, pp. 19, fig. 1).—This bulletin deals with Alabama (Aletia) argillacea, its biology, and preventive and remedial measures.

A contribution to the knowledge of the pine spinner Lasiocampa (Gastropacha, Dendrolinus) p CPI, K. Eckstein (Zool. Jahrb., Abt. System., Geogr. u. Biol. Tiere, 31 (1911), No. 1, pp. 59-164, pls. 6, figs. 3).—This is a report of extensive studies of the life history, bionomics, enemies, and economic importance of this lepidopterous enemy of the pine. A bibliography of 103 titles is appended.

The Colorado potato beetle, L. de la Barreda (Estac. Agr. Expt. Rio Verde, San Luis Potosi, Bol. 4, 1910, pp. 16, pls. 4).—This is a popular account of the potato beetle as it occurs in Mexico, with directions for the application of remedial measures.

Report upon tobacco insect investigations, G. A. Runner (Virginia Sta. Rpts. 1909-10, pp. 30-33).—The author, an agent of the Bureau of Entomology of this Department, reports briefly upon investigations of the tobacco stalk borer (Crambus caliginosellus), conducted largely at Appomattox, Va.

This borer, which is said to be the most important tobacco insect in Virginia, is found in most, if not all, the tobacco-growing sections of the State. The damage to the tobacco crop alone is estimated to average at least $500,000 annually and it is thought probable that the damage to the corn crop amounts to even more than that to tobacco.

"The tobacco is attacked soon after planting, and feeding continues until about the first or second week in July. The worms commence feeding just below the surface of the ground. Injured plants may usually be detected by their stunted or wilted appearance. This is more noticeable during hot, dry weather. The stems are in some cases entirely cut off, although this is rather unusual. The worms as a rule commence to feed on the outer portions of the stalk, a short distance below the surface of the ground. As feeding continues, the larvae, especially the smaller ones, enter the stalks and tunnel upward, the burrows frequently extending to the base of the first leaves and to some distance above the surface of the ground. When not feeding the worms are usually found in cylindrical web-lined galleries which extend from the plant, often several inches beneath the surface of the soil. The insects pupate in the soil, near the plants on which they feed. The adult moths emerge during late July and in August. The eggs are deposited, apparently at random, over weedy fields, soon after the moths emerge. Most of the eggs have hatched by the first of September.

"Where the worms are numerous it is almost impossible to secure a perfect stand of tobacco until late in the season, as the larvae remain in the ground and attack the plants set in place of those first injured or killed. Frequent replanting is necessary, the first planting sometimes being almost entirely destroyed. Many of the plants attacked partially recover from the injury, but remain dwarfed or stunted. . . . Early planted tobacco is usually better in quality and brings a better price than late-planted tobacco, but where the worms are numerous, early planting seems out of the question.

"Injury is greatest where tobacco is planted on weedy land, owing to the fact that the roots of certain weeds are the main food of the worms. From the data obtained during the past season, it is evident that clean cultivation of the land for some time previous to planting tobacco will be found effective in keeping the worms in check. Crops which are immune from attack by the worms (preferably leguminous crops) should be grown the year before the land comes in tobacco, and the ground kept free from weeds.

"As with tobacco, the injury is greatest when corn is planted on land which has been weedy pasture or meadow previously; or when planted on land which has not been under cultivation for a number of years and on which there is a
rank growth of weeds. On such land it is often very difficult to secure a satisfactory stand of corn. In Appomattox County, certain fields under observation were replanted several times, and owing to the lateness of the season when a stand was secured, the value of the crop was decreased fully 50 per cent.

"The worms attack the young corn just below the surface of the ground and burrow into the base of the stalks. The outer portion of the stalk is frequently girdled. If the stalks are small when attacked, they are either killed or so stunted or dwarfed that they never fully outgrow the injury, and produce little or no grain. Much of the corn is destroyed just as the seed is sprouting. When the stalks reach a height of 1 ft. or more, comparatively little damage is done. Several larvae are often found about the roots of a single stalk. As many as 22 have been collected from one hill of corn. Injury is not apt to be as severe in wet weather, as the plants are more vigorous and better able to withstand the attacks of the worms. In wet weather, weeds which furnish suitable food for the worms are apt to be plentiful, and these are attacked in preference to the corn."

A careful study of the life history and seasonal history of this species is under way, and attention is being given to field experiments with various methods of control. As a number of common weeds have been found to be natural food plants of the worms, a rotation of crops intended to keep the weeds in check will assist in reducing the number of worms in the field.

The palm weevil as a sugar cane pest, L. H. Gough (Dept. Agr. Trinidad Bul., 10 (1911), No. 67, pp. 59-64, pl. 1).—The author reports having observed during a visit to San Fernando a field of sugar cane in which 25 per cent of the plants had been killed, and many more injured or checked in their growth, by the palm weevil (Rhynchophorus palmarius).

Isle of Wight bee disease (Bd. Agr. and Fisheries [London], Leaflet 255, 1911, pp. 2).—A brief account is here given of the epidemic disease that first attacked bees in the Isle of Wight and has since reached the mainland, where it appears to be spreading. A description of the symptoms and a plan of procedure to be followed upon its appearance among bees are included in the account.

Two new insect pests in Nebraska (Forestry Quart., 8 (1910), No. 4, pp. 411-414).—In the first paper, which is entitled A New Insect Enemy of the Western Yellow Pine (pp. 411-413), L. Bruner reports that a sawfly resembling Lophyurus townsendi has been found to defoliate western pine in the northwestern part of the State, brief notes on its biology being included in the account.

In the second paper, entitled The Pine-Tip Moth (Retinia frustrana), M. H. Swenk reports that for the past 2 seasons young pines growing upon the National Forest at Halsey, Nebr., have suffered quite severe injury through the ravages of this insect. A careful examination made in July, 1909, showed that 35 per cent of the new tips were affected, practically all of which were dead and brown. "The trees most injured were in the older parts of the plantations where the jack pine was about 6 ft. tall with smaller Scotch pine scattered among them. During the past season, 1910, these injuries have spread to practically all the young pines on the forest and the attack was noticeably more serious, the injured twigs exceeding 50 per cent of the entire number and on some trees including nearly every new shoot."
"The insect is at least 2-brooded in this locality; the injury by the first brood of larvae becoming manifest by the middle of June, at which time the larvae are approaching full size and the older ones are already going into the pupa condition. The pupal stage is of short duration and the moths commenced to emerge by June 28 and continued coming out for nearly a month. The majority of the moths had emerged by July 10. In late July and early August the tiny larvae of the second brood may be found working in the terminal buds, and, as this brood develops, the previous injury is duplicated. The egg of the moth is a small, flat, yellowish object and seems to be usually deposited near the extreme end of the young tips so that the larvae on hatching burrow immediately into the tender bud and, as it develops, they form a cavity from 1 to 3 in. in length. When full grown, the insect pupates near the terminal end of the infested tip. This burrowing causes the death of the tip, and, as the needles rapidly turn brown and drop off, the injury becomes very conspicuous. On the National Forest the principal injury occurs on jack pine but the Scotch pine and western yellow pine are also affected. A considerable amount of parasitism is present among the tip moths, a small, black ichneumon fly and a chalcis fly being the principal parasites." An entomophilous fungus was also at work during 1910.

A new sawfly enemy of the bull pine in Nebraska, M. H. Swenk (Nebraska Sta. Rpt. 1910, pp. 3-33, figs. 18).—In May, 1910, reports were received to the effect that the pines east of Crawford were being stripped of their needles by worms. It was found that the region of greatest infestation lay in an elevated portion of Pine Ridge, east of the town of Belmont.

Specimens received and bred to adults were found to represent a new species of sawfly, closely related to Diprion (Lophyrus) townsendi. Rearing cage experiments showed that the larva, while preferring the foliage of the bull pine or rock pine (Pinus scopulorum), also fed eagerly upon needles of the closely related Austrian pine (P. austriaca) and to a limited extent upon the Scotch pine (P. sylvestris).

The larvae of this sawfly are conspicuously gregarious and occur in bunches of from 25 to 50 or 75 among the needles at the tips of the branches. The larva which hibernate in the trees become active in the spring and are nearly full grown by May 1, at which time the tops of the trees have been conspicuously denuded. By this time they stop feeding to any great extent in the day time and soon thereafter begin dropping to the ground to spin up. At the time of the author’s first visit on May 29, the larvae were very abundant on the trees but were said to be much less so than they had been a week or 10 days previously. By June 10 they had almost disappeared from the trees. In rearing cages the first larva spun up May 25 and the next on May 30; this continued until June 27 when the last of 69 larvae spun its cocoon.

Pupation apparently begins in early June and extends over at least a month. The first adults were found in the field on June 10 and by July 7 and 8 the adult females were common on pine tips. A small clump of young larvae of the new generation was found in the field as early as July 8, these probably representing exceedingly accelerated individuals, the progeny of adults which issued in early June. By October 27 the larvae had become half grown and had made very obvious defoliations. About this time they apparently cease active feeding and do not grow perceptibly until the following spring. Hibernation takes place in 2 distinct ways, namely, as half grown larvae in the trees and as fully developed larvae tightly packed in cocoons in the ground. The larvae which hibernate in cocoons in the ground, at least in part, are thought by the author to be those which have spun up after having become full grown the preceding season.
The tryphonine ichneumonid *Excentrus lophyri* is said to be a powerful enemy of this sawfly. Out of 60 cocoons containing larvae July 13, 30 were found to be parasitized, this representing 35 per cent of 85 cocoons examined. Two other ichneumonids, namely, *Phygadeuon (Mastrus) neodiprioni* and *P. (Bathyteutis) palinurus*, were reared but were not seen in the field and are thought to be of inconsequential importance. Several species of tachinids were found in the infested locality, the most common of which was *Euphorocera claripennis*. This species emerged July 1 and 8 from 2 larvae which spun up June 11. An undetermined bombylilid emerged July 25 from a cocoon collected July 8.

Other natural enemies mentioned are chipmunks (*Eutamias pallidus*), the mountain pine grosbeak (*Pinicola enucleator montana*), and western tanager (*Piranga ludoviciana*). A bacterial disease caused the death of many of the larvae.

No practical means of artificial control has been suggested. It is pointed out that burning over the grass and fallen needles in the fall would control but partially as this species spins its cocoons chiefly in the ground where it would be out of reach of the fire. Observations indicate, however, that the outbreak is being brought under control by the natural enemies. The author considers it probable that the affected area will not be further extended and that the injury will distinctly abate in intensity during the next season or two.

Some new species of reared ichneumon flies, H. L. Vierbeck (*Proc. U. S. Nat. Mus.*, 39 (1911), pp. 401–408).—Eleven genera and as many species are described as new to science, namely: *Meteorus lophyri*, bred from *Loxostege sticticallis*, at Rocky Ford, Colo.; *Schizoprymus phillippi*, bred from timothy, at Richmond, Ind.; *Chelonus shoeshonorum*, probably parasitic on *Argyresthia* sp., at Colorado Springs, Colo.; *Apanteles betheli*, parasitic on *Argyresthia* sp., at Colorado Springs, Colo.; *Microgaster complana*, bred from *Aegilis complana*, at Rocky Ford, Colo.; *Heterospilus mordellistena*, parasitic on *Mordellista ustulata*, at Wilmington, Ohio; *Lumicrinum (Horogines) discoccellina*, bred from *Gelchia discooccellina*; *Excentrus lophyri*, reared from *Lophyris thunscudii*, at Crawford, Nebr.; *Phygadeuon (Exoplera) ascal*, reared from the cocoon of a species of (Hylotoma) Arge, at Marietta, Ohio; *Phygadeuon (Polytribax) pallescens*, reared from the chrysalis of Hyphantria, and of *Eudamus (Epargyrcus) tityrus* at Castle Rock, Pa.; and *Mesochorus perniciosus*, bred from *Loxostege sticticallis*, at Rocky Ford, Colo., and probably a hyperparasite of *Apanteles lavoeps*.

Notes on some parasites of *Agrotis segetum*, N. Kurbiumov (*Russ. Ent. Obozr.*, 11 (1911), No. 1, pp. 48–53).—The parasites noted are *Oophysora semblidis*, *Gonia capitata*, and *Cnephalia* sp.

On the parasitic Hymenoptera collected by Mr. A. J. T. Janse, Transvaal, P. Cameron (*Ann. Transvaal Mus.*, 2 (1911), No. 4, pp. 173–217).—This paper presents descriptions of a large number of new genera and species of parasitic Hymenoptera, together with records of the hosts of a number.

Tischeria complanellia and of Myopites limbardii. See also a previous note (E. S. R., 22, p. 59).

The zocecidia of plants in Germany and their occupants, edited by E. H. RüsSAAIENCE (Zoologica, 24 (1911), No. 61, pt. 1, pp. 293, pls. 6, figs. 3).—The first paper of this work (pp. 1–104), by F. Thomas, consists of an index of the literature up to the close of 1906 on the animal galls of Germany and their occupants. The second paper (pp. 165–165) consists of a general account by E. Küster of animal galls and their occupants. The third paper (pp. 167–293), by A. Nalepa, is devoted to the criophyll gall mites, their structure, development, ecology, and classification.

The animal kingdom.—Ixodidae, L. G. Neumann (Das Tierreich.—Ixodide. Berlin, 1911, No. 26, pp. XVI+169, figs. 76).—In this systematic treatment of the ticks, the author divides the family Ixodidae into 2 subfamilies, namely, the Ixodinae, including the sections Ixodini and Argatini, and the Spelacorhynchinae, represented by the single species Spelacorhynchus praeceptor described by Neumann in 1902 from a specimen collected from a bat (Carollia brevicuda) in Pernambuco.

The section Ixodini is divided into 3 tribes, namely, Ixodaria, including the genus Ixodes with the 3 subgenera Ixodes, Ceratixodes, and Eschatocephalus; Rhipicephalinae, including the genera Rhipicephalus, Margaropus, and Hyalomma; and Amblyommataria, including the genera Amblyomma, Aponomma, Dermacentor, and Haemaphysalis. The section Argatini is represented by the genera Argas and Ornithodoros.

A synonymical bibliography and description, together with host and distribution lists, is given for each species. Tables for the separation of species, a systematically arranged host list, and an index are also included.

The preparation of this work was completed on February 29, 1908.

Ticks: A monograph of the Ixodoidea, II.—Ixodidae, G. H. F. Nuttall and C. Warburton (Cambridge, 1911, pp. XIX+105–348, pls. 4, figs. 193).—This second part of the authors’ monograph (E. S. R., 21, p. 562) is divided into two sections, the first dealing with the classification of ticks, and the second with the genus Ixodes.

Under the genus Ixodes the authors give the synonymy and literature, and keys for the determination of the species based upon males, females, nymphs, and larvae so far as the material at hand has permitted. Technical descriptions of 51 species which the authors consider valid and of varieties and subspecies follow. The synonymy, iconography, bibliography, descriptions of the stages, and geographical distribution are given for each species. These detailed accounts of the species are followed by a list showing the geographical distribution of the genus, a list of condemned and doubtful species of Ixodes, including their synonymy and literature, notes on doubtful species of Ixodes, and notes on the biology of Ixodes by G. H. F. Nuttall (pp. 294–317). Two appendixes include reprints of papers (1) on The Process of Copulation in Ornithodorus moubata (pp. 318–323), by G. H. F. Nuttall and G. Merriman, and (2) On the Adaptation of Ticks to the Habits of Their Hosts (pp. 324–345), by G. H. F. Nuttall. An index to the valid species of Ixodes, together with a list of the collections in which the types are to be found, is included.

Ticks: A monograph of the Ixodoidea.—Bibliography of the Ixodoidea, G. H. F. Nuttall, L. E. Robinson, and W. F. Cooper (Cambridge, 1911, pp. VI+68).—This bibliography, which contains 2,004 titles, deals with ticks and their relation to disease. It is arranged by authors, and includes the date of publication.

Spirochætes, a review of recent work with some original observations, W. C. Bosanquet (Philadelphia and London, 1911, pp. 152, pl. 1, figs. 90).—Section 1 of this work (pp. 11-71) deals with the general characters of spirochetes. Section 2 (pp. 72-116) consists of systematic descriptions of the species. A bibliography of 20 pages arranged by subjects, species, etc., and bibliographic and subject indexes are included in the work.

A preliminary note on the extrusion of granules by trypanosomes, W. B. Fry (Proc. Roy. Soc. London, Ser. B, 81 (1911), No. 5, pp. 35, 39).—The author has found that at times during the course of an infection certain of the trypanosomes extrude from their bodies granules which are thrown off, apparently with considerable force, and then appear to possess a certain motility of their own in the blood.

Spraying trees with zinc arsenite, E. E. Luther (Better Fruit, 5 (1911), No. 8, pp. 65, 66).—It is stated that investigations in the Pajaro Valley, Cal., have shown that zinc arsenite can be used on apples with safety, it having been sprayed as thick as heavy whitewash without the slightest injury. "On small field crops, such as beans, potatoes, etc., it has given no injury, but on the peach, which is supposed to be more hardy than the bean, the injury was severe." It is readily suspended, requiring little or no agitation, has a great covering power, is highly toxic for insects, and much cheaper than arsenate of lead. The author states that "the equivalent of 12 cts. of arsenate of lead can be purchased in this material for less than 5 cts."

Zince arsenate, A. Desflassieux (Prog. Agr. et Vit. (Ed. l'Est-Centre), 32 (1911), No. 12, pp. 358, 359).—The author has found the results obtained from the use of zinc arsenate as an insecticide to be similar to those from lead arsenate. Among the advantages that it has over lead arsenate, mention is made of its lightness, the fact that even if used in excess it does not precipitate when added to copper mixtures, and the absence of the dangerous action of lead salts on man, zinc having an emetic rather than toxic action.

The formula recommended consists of arsenate of soda 200 gm. and zinc sulphate 475 gm., the latter to be dissolved in 10 liters of water and added to the arsenate of soda dissolved in a few liters of water. This stock solution should be diluted to make 100 liters or added to a copper mixture, if desired, and diluted to 100 liters.

An index to Circulars 1 to 100 of the Bureau of Entomology, R. P. Currie and A. N. Caudell (U. S. Dept. Agr., Bur. Ent. Circ. 160, pp. 49).—The index of these circulars is preceded by a list of Circulars 1 to 100, with their revisions. It is stated that this list may be considered final since the policy of issuing revised editions of circulars, that is, under the original serial number, has been discontinued. For circulars which have gone through one or more revisions the latest edition is the one indexed.

FOODS—HUMAN NUTRITION.

Wheat and flour investigations (Washington Sta. Bul. 100, pp. 52, figs. 2).—This bulletin consists of three parts.

I. Analyses and tests of crops of 1908 and 1909, R. W. Thatcher, G. A. Olson and W. L. Hadlock (pp. 3-24).—In continuation of earlier work (E. S. R., 23, p. 467), analyses are reported of a large number of samples of Washington wheats. Striking differences were not noted in the samples of the crop of 1908 as compared with wheats previously analyzed, though, in general, the moisture content was lower. In samples of the crop of 1909 this was also noticeable, and variations in the relative protein content were significant. Of
the varieties most commonly grown Bluestem again headed the list with the highest protein content. Red Allen being next in protein content, gluten test, and high yield of flour, while Turkey Red showed considerably lower average protein content compared with other varieties than in previous years, although the average wet gluten tests of the flour did not show so marked a falling off. The continually lower rank held by Turkey Red wheat in protein content over the 5 years the investigations have been carried on indicates that this variety grown longer under local conditions "tends to lose its relatively high protein content as compared with other fall-sown varieties."

II. The composition and milling quality of Washington wheats, R. W. Thatcher (pp. 25-44).—The subject is discussed on the basis of the analyses of 431 samples of wheat reported in this and earlier bulletins, of which 349 samples represent the 7 varieties most commonly grown in eastern Washington, namely, Bluestem, Little Club, Turkey Red, Jones Winter Fife, Fortyfold, Red Allen, and Red Russian. Thirteen represent macaroni or durum wheat, and 8 each Sonora and White Amber, the remainder being varieties grown in small quantities or in limited areas.

Considerable variations were noted in the water content and the nutrients present in the different varieties and in different samples of the same variety. This subject, and particularly the effect of rainfall and climatic conditions on protein content, is discussed with reference to the wheats grown in different parts of the State and with reference to the broader question of the effect of climatic conditions on the composition of wheat. In general, the author believes that there are certain definite variety differences in composition which can be "correlated with the habits of each variety as to rapidity of ripening, and that these variations are due to the relative length of ripening period, as a variety characteristic, and, therefore, come under the same general rule as do all other observed variations in type or composition. Final conclusions on this matter must be suspended until sufficient data as to the ripening habits of the different varieties have been secured."

III. A simple apparatus for determining the milling qualities of wheats, G. A. Olson (pp. 45-52).—An inexpensive outfit for milling wheat is described and tests reported in comparison with a commercial experimental mill which showed that it gave accurate results, the largest variation recorded being 2.6 per cent less bran and shorts with Bluestem wheat than was obtained with the commercial experimental mill. On an average 119 samples representing different varieties of Washington wheats gave 27.37 per cent bran and shorts and 72.77 per cent flour. Owing to the absorption of water some of the samples gained weight during milling, the average amount being 1.01 per cent, and either owing to drying or unavoidable losses other samples lost in weight, the average being 1.21 per cent. The wide variations observed in the yield of bran, shorts, and flour "show the importance of milling samples of wheat in order to determine the relative value of different wheats which are sold."

Milling tests of wheat and baking tests of flour, J. T. Willard and C. O. Swanson (Kansas Sta. Bul. 177, pp. 29-153, figs. 25).—Information is summarized regarding methods of cleaning wheat followed in some Kansas mills, and the results are reported of experimental studies on the milling of wheat, chiefly of the crops of 1906 and 1907, and of baking tests with the resulting flours. In addition, germinated wheat was compared with sound wheat, and the milling and baking qualities of wheat as affected by moisture and heat were studied. The general purpose of the investigation has been to trace, if possible, connections between the chemical compositions of wheats and flours and their milling and baking qualities. The investigations include detailed analyses...
of about 60 wheats, with milling and baking tests, the latter including in many cases comparisons of patent, break, and tailings flour from the same grinding. A considerable amount of milling and baking apparatus specially designed for experimental work is described, including a new design for test baking-pans.

According to the authors, the investigations show that "the baking results are influenced very greatly by a large number of details, and that while the gliadin-protein ratio may be of some importance its effect may be entirely offset by the influence of other agencies. The special baking experiments recorded show how easily results may be modified by variations in the amount of water or yeast used, differences in the extent of the rising, in the working of the dough, in the fineness of the flour, in the initial temperature of baking, etc.

"The effect of germination of wheat on the baking qualities of the flour which it may yield was shown to be pronounced, but not of the character that might have been anticipated. Slight germination injured the bread but very little. The effect of heat upon the bread making power of wheat was very marked. Moist wheat dried at 100° C. to 120° C. was ruined for this purpose."

Bread as made in Milan, E. Galli (Rend. Soc. Chim. Ital., 2, ser., 2 (1910), pp. 179–187).—Recommendations are made for improvements in bread making in Milan, which are based on the results of an experimental study.

The bread question. J. S. Wallace (Brit. Med. Jour., 1911, No. 2648, pp. 437, 438).—In connection with a discussion of the relative nutritive value of bread of different sorts, particularly with reference to food as a factor in dental caries, experiments are reported on the efficiency, for the removal of bacteria on teeth, of different sorts of food when masticated.

The author believes it is fairly safe to conclude that "no farinaceous foodstuff in general use in this country is less harmful to the teeth than bread when eaten with butter, and no farinaceous foodstuff is more beneficial from the point of view of oral hygiene: especially is this the case when the bread is eaten with butter and a goodly proportion of crust.

"The different varieties of bread (that is, white, standard, and stone-milled) make no appreciable difference in inducing dental caries, beyond the difference which the physical differences of the bread make in their deterrent effects on the teeth.

"The crust is always preferable to the crumb in all varieties of bread. Similarly, toasted bread of any variety is preferable to untoasted bread of any variety.

"The amount of phosphates or proteid absorbed from one kind of bread may be greater than from another kind. It is said that more phosphates are absorbed from white than from coarse whole-meal bread. From the point of view of dental caries, this does not seem to be of any consequence whatever."

The composition of diabetic foods. F. W. F. Arnaud (Brit. Food Jour., 13 (1911), No. 152, pp. 143, 144).—In a paper read before the British Pharmaceutical Conference, July, 1911, the author reports and discusses the results of analyses of a number of commercial diabetic foods. In a majority of the samples examined the starch content was high, and "it would appear to be expedient that some steps should be taken for the repression of the business carried on in the sale of ordinary bread and flour as specially prepared diabetic foodstuffs, or the composition of these foodstuffs should be declared to the purchaser."

The effect of low temperatures on ground chicken meat, H. W. Houghton (Jour. Indus. and Engin. Chem., 3 (1911), No. 7, pp. 497–505).—Chicken meat subjected to cold storage even for a period of 5 months, the author concludes from his extended analytical studies, exhibits certain physical and chemical
changes which show clearly that it is not identical with fresh material. The cold storage meat was soft, in marked contrast to fresh chicken meat, and had a slightly characteristic odor.

"The chemical changes that apparently take place in the cold-stored meat by direct comparison with the original chicken meat are (1) slight variations of moisture and ether extract; (2) a small increase of ammonia, especially in the case of the light chicken meat; (3) a decided increase of water-soluble nitrogen, total solids, and organic extractives in the light chicken meat, with a slight decrease of the same constituents in the dark meat; (4) a decrease of congelable nitrogen in both varieties of chicken meat during the first 30 days, followed by a rise which did not reach that of the fresh sample; (5) an increase of amino acids in both kinds of chicken meat, with an increase and decrease of the proteoses and peptones respectively in the light and dark chicken meat.

"An increase of soluble phosphorus was indicated during the first 90 days of the storage period, which was more marked in the dark meat than in the light meat. In the cold-stored samples a little volatile sulphur was found, none being detected in the fresh meat. The analyses of chicken fat indicated a fairly constant composition, but in the chicken meat fat of the cold-stored chicken the iodin number increased regularly while the index of refraction decreased slightly.

"The alteration particularly noticed in the light meat was inhibited to a certain extent by storing in an atmosphere of carbon dioxid, accompanied by an increased production of proteoses, peptones, and amino acids. The initial increased production of these nitrogen bodies is probably due to enzymic action during the first 30 days at 12° C.

"The enzymes detected were peroxidase, catalase, protase similar to trypsin, invertase, and a nitrate-reducing enzyrn."

The inspection of fish at the Paris central market, Blanchard (Hyg. Viande et Lait, 5 (1911), Nos. 3, pp. 149-157, figs. 19; 5, pp. 283-289, figs. 11; 7, pp. 404-411, figs. 11; 8, pp. 466-474, figs. 12).—Illustrated descriptions are given of the fish found in the Paris market.

The composition of the apple as affected by irrigation, C. E. Bradley (Jour. Indus. and Engin. Chem., 3 (1911), No. 7, pp. 496-497).—In general, the results showed that apples from irrigated plats had a somewhat higher moisture content and consequently lower total solids, but higher percentages of sugar, than apples from unirrigated plats.

"The protein content of the peelings tested averaged 0.70 per cent while that of the edible portion was 0.29 per cent. Only traces of starch were present in the samples tested.

The abuse of sweetmeats, A. Hopewell-Smith (Brit. Med. Jour., 1911, No. 2643, pp. 438-442, qmns. 2).—An experimental study is reported of the effects of confectionery, including chocolate, upon caries-forming bacteria. The conclusions reached were not favorable to the use of sweetmeats, particularly by children.

The paper is followed by a discussion.

Food accessories, stimulants, and narcotics, C. Hartwich (Die Menschlichen Genussmittel. Leipsic, 1911, pp. XIV+878, pls. 24, figs. 168).—The author has included in this volume a large amount of data regarding the origin, history, use, and effects of such articles as tea, coffee, cocoa, chocolate, and mate, as well as information of the same sort regarding stimulants and narcotics used in different parts of the world.

the English pure food laws are listed, terms defined, administration work and methods of enforcement considered, and the principal food laws discussed in some detail.

Notices of judgment (U. S. Dept. Agr., Notices of Judgment 1035, pp. 3; 1036-1036, p. 1 each; 1041-1043, pp. 2 each; 1043, pp. 7; 1044, pp. 8; 1045, pp. 5; 1046-1048, p. 1 each; 1049, pp. 10).—These notices of judgment have to do with the adulteration of mushrooms, "creme wafels," preserved whole eggs, tomato catsup, frozen eggs, and black olives; the misbranding of sugar corn flakes and two drug products—"radio-sulpho" and "radio-sulpho brew"; the adulteration and misbranding of elder vinegar, preserved peach, apple, and sugar, special wild cherry soda water flavor, pistachio extract, and grape juice; and the alleged misbranding of oxidin.

Food and feeding in health and disease—a manual of practical dietetics, C. Watson (Edinburgh and London, 1910, pp. XVI + 638, pls. 17, diagrams 8).—This volume contains chapters on food and its functions, different groups of foodstuffs, patent, proprietary, and predigested foods, diet for persons of different ages, and other general topics, as well as on diet in diseases of different sorts, diet cures, and similar subjects.

In an appendix the author has reprinted the results of investigations carried on by himself and his associates regarding the effects of diet on the structure of animal tissues.

The volume is provided with a comprehensive index.

The feeding of necessitous children (Lancet [London], 1911, II, No. 4, pp. 239, 240).—A brief summary, based on a report by D. Forbes and J. Lambert, of the results obtained in feeding needy school children. According to the data summarized, often the first gain which an ill-nourished child makes on being properly fed is in height.

The cost of living, salaries, and wages in Trieste in the last quarter of a century, M. Alberti (Il costo della vita, i salari e le paghe a Trieste nell'ultimo quarto di secolo. Trieste, 1911; rev. in Economist, 73 (1911), No. 3545, pp. 297, 298).—Information is given regarding the kinds of food used, as well as statistical and other data such as would be indicated by the title.

Housekeeping efficiency, C. and Mary Barnard (Housekeeping Expt. Sta. [Conn.] Buls. 11, pp. 20, pls. 3; 12, pp. 20, figs. 5).—Increased efficiency through correct house planning, the use of conveniences and labor-saving devices, and the elimination of needless work are discussed, and data recorded regarding the actual labor involved in performing a definite task by different methods.

Soyer's paper-bag cookery, N. Soyer (New York, 1911, Amer. Ed., pp. 130).—A method of cooking meats and other foods enclosed in specially prepared paper bags is described, which it is claimed is economical of time, labor, and fuel, and which retains flavors. Many recipes for the preparation of individual dishes are given.

Paper-bag cookery, J. L. Griffiths (Daily Cons. and Trade Rpts. [U. S.], 14 (1911), No. 163, pp. 206, 207).—A summary of data on the system of cookery referred to above.

Paper-bag cookery, R. Westacott (Daily Cons. and Trade Rpts. [U. S.], 14 (1911), No. 206, p. 1099).—A note regarding the bags used in this method of cookery.
Feeding experiments with isolated food substances, T. B. Osborne, L. B. Mendel, and Edna L. Ferry (Carnegie Inst. Washington Pub. 156, 1911, pp. 53, fig. 1, dyns. 21).—In this paper, which may be regarded as a progress report, problems of nutrition are reviewed in the light of the newer knowledge of the chemical structure of proteins. "The possibilities of protein synthesis in animals and the conditions which this postulates; the significance of the availability, palatability, and physical texture of the food intake; the suggested rôle of various accessories—inorganic salts, lipoids, etc.; the distinction between the nutritive demands during the period of growth and those of later adult life, are brought within the range of discussion."

A large number of experiments are reported with white rats to determine whether animals can be maintained in nitrogen equilibrium and health for long periods on a diet consisting of a constant mixture of pure foodstuffs, including a single proteid. "Numerous experiments are reported in which casein formed the sole nitrogenous constituent of the dietary. In this connection it is shown that the make-up of the inorganic constituents of the diet exercises an influential effect on the nutritive efficiency of the dietary. From the experience thus gained a 'basal' ration was constructed on which rats were kept many months in good health. Some of these experiments in which the animals exhibited no noteworthy alterations in weight and showed a good gain in nitrogen are, as far as the authors are aware, the most successful recorded attempts at artificial nutrition with a constant mixture of pure foodstuffs, containing only a single protein. Satisfactory experience also followed the gradual complete substitution of the casein by other proteins, one animal continuing more than 217 days on a diet in which the sole protein was glutenin."

Relation between the digestibility and the retention of ingested proteins, D. D. Van Slyke and G. F. White (Jour. Biol. Chem., 9 (1911), No. 3-4, pp. 219-229).—The rate of nitrogen excretion was studied on different diets by collecting urine at intervals and determining its nitrogen content, the rate of nitrogen excretion being taken as an index of the rate of absorption in the intestine. Adding starch to the diet decreased the rate of nitrogen metabolism but did not affect the completeness of absorption. With the foods tested nitrogen excretion occurred most rapidly after the ingestion of cod. The lower cleavage products appear to be less capable than the higher cleavage products of maintaining nitrogen equilibrium.

The chemical and energy transformations in the dog after the ingestion of different quantities of meat, H. B. Williams, J. A. Riche, and G. Lusk (Proc. Soc. Expt. Biol. and Med., 8 (1911), No. 3, pp. 61, 62).—Experimental data are summarized and briefly discussed.

Calcium metabolism.—II, The calcium content of human blood after oral administration of large doses of calcium, N. Voorhoeve (Biochem. Ztschr., 32 (1911), No. 5-6, pp. 394-409).—The daily administration of 2.727 gm. of calcium oxid in the form of lactate or chlorid increased the calcium content of the blood of a man on a diet rich in calcium. Under similar conditions 0.545 gm. of calcium oxid did not cause a very appreciable increase.

Certain fundamental principles relating to the activity of bacteria in the intestinal tract—their relation to therapeutics, A. I. Kendall (Jour. Med. Research, 25 (1911), No. 1, pp. 117-187).—From a consideration of available data and the results of a number of experiments with infants with bacillary dysentery, the author concludes that carbohydrates protect protein in bacterial growth, a conclusion similar to a theory quite commonly accepted in animal nutrition.
"Bacteria in the presence of protein, or protein decomposition products, and fermentable carbohydrate act upon the carbohydrate in preference to the protein, because utilisable carbohydrate shields protein from bacterial attack."

The data presented are discussed chiefly with reference to their bearing upon diet in disease.

"The harmful effects of bacteria are associated to a considerable degree with their action upon protein; it can be shown experimentally that the organism concerned in the production of bacillary dysentery act thus, and it can further be shown that the introduction of utilisable carbohydrate tends to prevent this elaboration of putrefactive or toxic products."

A bibliography is appended to the paper.

**The effect of the environment of carbonated beverages on bacteria, C. C. Young and N. P. Sherwood (Jour. Indus. and Engin. Chem., 3 (1911), No. 7, pp. 495, 496).—Investigations were undertaken to determine whether or not any pathogenic organism could withstand the unfavorable environment of bottled carbonated beverages a sufficient length of time to reach the consumer. It was found that the number of organisms in the beverages examined was extremely small except for those which had been introduced.**

"There was a decided reduction in number of the organisms introduced, owing to standing 244 hours uncarbonated.

"There was a very marked reduction in numbers of all three organisms introduced, and especially of Bacillus typhosus, owing to conditions existing in the carbonated bottles.

"There was not a complete killing out of the organisms introduced, during the entire experiment.

"B. prodigiosus and B. coli seemed to be somewhat more hardy than B. typhosus.

"Undoubtedly the longevity of B. typhosus depends in a great measure upon the virulence of the organism, and as the results above show that some of the organism will live longer than the beverage is normally on the market, the manufacturer should not depend upon the percentage of reduction caused by the carbon dioxid and other substances used.

"From the observation that the most hardy individuals can resist these adverse conditions for a considerable length of time, the logical conclusion is that no water should be used in the manufacture of a carbonated drink that is in the least suspicious, and if a doubtful water is the only source of supply, this should be subjected to treatment by some method of sterilization with subsequent filtration through a trustworthy and efficient filter."

**A study of the influence of rice diet and of inanition on the production of multiple neuritis of fowls and the bearing thereof on the etiology of beriberi, W. P. Chamberlain, H. D. Bloomergh, and E. D. Kilbourne (Philippine Jour. Sci., B. Med. Sci., 6 (1911), No. 3, pp. 177-209, pls. 4, figs. 5).—From the experimental evidence the conclusion was reached that fowls developed multiple neuritis "when fed exclusively on polished rice, whether Filipino No. 1 or Saigon choice rice is used. . . .

"Those fowls that voluntarily eat heartily of polished rice are able thereby to maintain their body weight and to defer or to prevent the development of multiple neuritis.

"The administration of certain inorganic salts of phosphorus and of potashium, either alone or combined, to fowls subsisting on polished rice neither prevented multiple neuritis nor deferred its onset."

Fowls fed unhusked rice, or undermilled (unpolished) rice, did not acquire the disease, nor did those fed on undermilled rice combined with large amounts of sodium chlorid.
"Fowls from which all food is withheld and only water allowed, develop multiple neuritis in some cases.

"Fowls starved on reduced amounts of a neuritis-preventing undermilled rice acquire multiple neuritis in some cases . . .

"The signs, symptoms, and nerve appearances are identical in neuritis produced by inanition and in that caused by feeding polished rice. . . .

"In neuritis-producing rice and in beriberi-producing dietaries both the phosphorus and the potassium are markedly reduced in amount, the latter in greater degree than the former.

"As an index of the beriberi-producing power of a given rice, reduction in the potassium content is probably quite as reliable as reduction in the phosphorus content."

Practical experiences with beriberi and unpolished rice in the Philippines, V. G. HEISER (Philippine Jour. Sci., B. Med. Sci., 6 (1911), No. 3, pp. 229-233).—Information is summarized regarding the efforts made to encourage the use of unpolished rice in the Philippines and the success which has attended it.

For purposes of convenience "a rice containing less than 0.4 per cent of phosphorus pentoxid is regarded as polished and that which contains a greater percentage of phosphorus pentoxid as unpolished rice."

An attempt to secure legislation regarding the use of unpolished rice in the Philippines is briefly discussed.

Studies on the protective power of bran in a polished rice diet, L. BREAUPAT (Bul. Soc. Path. Exot., 4 (1911), No. 7, pp. 498-502).—In experiments with chickens rice bran and a corresponding amount of an aqueous extract of rice bran exercised a protective effect. A study of the nitrogen content showed that the protective power was not directly ascribable to the additional amount of nitrogen supplied. The absence of fat, cellulose, starch, etc., in the extract was additional evidence of the inactivity of these substances in preventing disease ascribable to the use of polished rice in large proportion.

Digestion in fever, J. B. NICHOLS (Amer. Jour. Med. Sci., 142 (1911), July, pp. 93-95).—From a summary of data on the subject the author concludes that the average reduction of digestion during fever is not over 5 to 10 per cent. The bearing of these facts on feeding in fever is discussed.

Organic matter in the expired breath, M. J. ROSENAY and H. L. AMOSS (Jour. Med. Research, 25 (1911), No. 1, pp. 35-84, figs. 5).—Using the reaction of anaphylaxis, the authors conclude from experiments in which the liquid obtained by condensing the moisture from the expired breath of man was injected into guinea pigs that the presence of organic matter in expired breath has been demonstrated.

"The logical conclusion from our results is that protein substances under certain circumstances may be volatile. It seems unlikely that such a complex molecule should possess the power of passing into the air in a gaseous form. The volatility, however, now in question may resemble that solubility which deals with particles in suspension in a physico-chemical state (colloidal suspension). The protein may simply be carried over in 'solution' in the watery vapor.

"Our experiments are too few to state that albuminous substances such as egg white, milk, or blood serum in vitro is 'volatile.' However, they are sufficiently suggestive to stimulate further work along this line."

A few experiments to determine the effect of time, temperature, acids, and alkalis upon the organic matter in the expired breath are recorded, but the data are regarded as too limited to warrant conclusions. "It is of practical importance to collect further information along these lines. It would also be
interesting to study the organic matter in the expired breath in health and disease; in different ages, etc. . . .

"The fact that the expired breath contains definite amounts of specific organic substances will also have an immediate bearing upon the problems of ventilation and the effects of vitiated air. There has recently been a growing tendency to regard the ill effects of vitiated air as due to the increased temperature and moisture, but it is now apparent that there are other factors which must be taken into account."

A respiration calorimeter of the Atwater-Rosa-Benedict type designed for use with dogs and children; with demonstration, H. B. Williams (Proc. Soc. Expt. Biol. and Med., 8 (1911), No. 3, p. 61).—A brief account of the completion of a respiration calorimeter of suitable size, and with special modifications, for the study of the gaseous exchange and energy metabolism of infants and small animals.

Origin and development of the nutrition investigations of the Office of Experiment Stations, C. F. Langworthy (U. S. Dept. Agr., Office Expt. Stus. Rpt. 1910, pp. 449-460).—Early nutrition work in the United States is considered as well as the origin of the nutrition work of this Department, its scope, the number and character of the publications which have been issued, and the practical results of the investigations.

**ANIMAL PRODUCTION.**

Lectures on biology, C. Thesing, trans. by W. R. Boelter (London, 1910, pp. VIII+334; rev. in Nature [London], 86 (1911), No. 2172, pp. 510, 511).—This is a translation of a German work (Biologische Streifzüge), which is a modern presentation of the biological investigations on variation, heredity, and adaptation, with a discussion of their value from the standpoint of philosophy.

On germinal transplantation in vertebrates, W. E. Castle and J. C. Phillips (Carnegie Inst. Washington Pub. 144, 1911, pp. 26, pls. 2).—This contains further details (E. S. R., 21, p. 609) on transplanting undeveloped ovaries in guinea pigs and rabbits and of testicles in rats. In the guinea pigs there were 2 cases where young were produced from the grafted tissue. The influence of the foster mother was negative in one case, and the other case was rejected because the apparent positive evidence can be accounted for as a recessive character.

The authors review the work of other investigations on ovarian and testicular transplantation (E. S. R., 24, p. 576) in poultry, mammals, and human beings.

A bibliography is appended.

On evidence of some influence on offspring from engrafted ovarian tissue, C. C. Guthrie (Science, n. ser., 33 (1911), No. 856, pp. 816-819).—A discussion of the work of Castle, noted above.

The transplantation of ovaries in chickens, C. B. Davenport (Jour. Morph., 22 (1911), No. 1, pp. 111-122).—The author performed 6 experiments in removing ovaries of hens and transplanting them to dissimilar hens, but found no evidence that the engrafted ovary ever became functional, as the more or less completely extirpated ovary regenerated and produced an abundance of eggs. There was no noticeable effect on the soma of the foster mother by the introduced germ plasm.
The fate of ovarian tissues when planted on different organs, C. R. Stock- and (Arch. Entwickl. Mech. Organ., 32 (1911), pt. 2, pp. 298-307, pls. 3, figs. 2).—With guinea pigs transplanted ovarian tissue did not live long, though longer when planted into the testicles than in the other organs. The fate of the transplanted tissues of salamanders depended largely upon the nature of the organ upon which the tissue was transplanted.

The regulatory process in organisms, C. M. Child (Jour. Morph., 22 (1911), No. 2, pp. 171-222).—A discussion of the significance of important work by different investigators on a wide range of phenomena of plants and animals, commonly called “regulation.” The organism is regarded as a physico-chemical system, with no necessity of assuming entelechy or other vitalistic hypotheses. The processes of metabolism in the single cell, known as chemical reactions, are considered as of the same nature as the regulation of vital organs, regeneration of lost parts, and reproduction; the processes of physiological equilibrium and equilibration constituting the phenomena of regulation, which is the fundamental problem of life.

“All of our experimental investigations of living organisms are directly concerned with the problem of regulation in one way or another. In fact, there are only two possible methods of investigating and analyzing the phenomena of life; one is concerned with regulation in the living organism, the other with the observation and analysis of results of stopping the life processes at this or that particular point.”

Further remarks on the chemical mechanics of cell division, T. B. Robertson (Arch. Entwickl. Mech. Organ., 32 (1911), pt. 2, pp. 308-313).—Various sources of error in McClendon’s experiments (E. S. R., 21, p. 575) are pointed out, and it is shown that oil droplets do not divide in alcohol-water mixtures containing more than 50 per cent of alcohol because of the presence of the alcohol and not because they are submerged. Results of the author’s experiments convince him that cell division is attributable to an equatorial diminution of surface tension, and he states that cell division due to an equatorial increase in surface tension is hydromechanically untenable.

Mitokinetism in the mitotic spindle and in the polyasters, M. Hartog (Arch. Entwickl. Mech. Organ., 21 (1909), pt. 1, pp. 141-155, figs. 6).—A reply to objections which have been raised by Baltzer to the author’s account of the forces involved in mitosis.

The continuity of mitochondria through successive generations and its significance, M. E. Fauré-Fremiet (Anat. Anz., 36 (1910), No. 5-7, pp. 186-191, figs. 3; abs. in Jour. Roy. Micros. Soc. [London], 111, No. 2, p. 190).—The development of mitochondria was found to accompany cell division and a continuity was thus established. There is a discussion as to their importance as carriers of heredity.

Some cytological corrections, L. C. Bragg (Amer. Breeders Mag., 2 (1911), No. 1, pp. 74-76).—The three errors referred to, which still persist as facts in most text-books on cytology and heredity, are (1) that there are a specific number of chromosomes in the germ cells of organisms, (2) that the gametes have an equal number of chromosomes, and (3) that the chromosomes may be used by the taxonomist in classification.

Chromosomes as bearers of heredity, H. E. Ziegler (Jahresh. Ver. Vaterländ. Naturk. Württemb., 67 (1911), pp. 588-595, figs. 4).—Affirmative evidence is cited to substantiate the view that inherited traits are chiefly transmitted by means of the chromosomes. Examples are given of the possible combinations and probable percentages of inheritance of characteristics, assuming that the germ cells of both parents contain 12 chromosomes each.
Studies on chromosomes.—VII. A review of the chromosomes of Nezera; with some more general considerations, E. B. Wilson (Jour. Morph., 22 (1911), No. 1, pp. 71–110, pl. 1, figs. 9).—In the latter part of this paper the author summarizes, under the following headings, the work on chromosomes which he has reported at various times and places for the past 6 years: (1) The idiochromosomes, (2) composition and origin of the X Y pair, (3) modifications of the X element, (4) sex limited heredity, and (5) secondary sexual characteristics.

Though believing that in the chromosomes we have the mechanism which may explain some of the phenomena of heredity, he does not think that they are the exclusive factors of determination. Sex limited heredity is seen to run parallel to the distribution of definite structural elements, and there is a remarkable consistency of the chromosome relation in the species. Skepticism regarding it is said to have no justification, though individual fluctuations do occur.

[The inheritance of complex growth forms, such as stature, and Mendel's theory.] J. Brownlee (Proc. Roy. Soc. Edinb., 31 (1910–11), No. 2, pp. 251–256).—The inheritance of complexes is illustrated by assuming a simple case where two races mix in equal numbers and the property in question depends upon two elements, and it is thereby shown that there is nothing necessarily antagonistic between the evidence advanced by the biometricians and the Mendelian theory.

"If the inheritance of stature depends upon a Mendelian mechanism, then the distribution of the population as regards height will be that which is actually found, namely, a distribution closely represented by the normal curve. There is nothing in the values of the coefficients of inheritance found by Sir Francis Galton and Professor Pearson which can not be explained on the basis of Mendelian inheritance."

The inheritance of the peculiar pigmentation of the Silky fowl, W. Bateson and E. C. Punnett (Jour. Genetics, 1 (1911), No. 3, pp. 185–203).—This is a study of the inheritance of the black pigment which is generally distributed among most of the mesodermal tissues of the body in Silky fowls.

Offspring of a Silky hen crossed with a Brown Leghorn male which never had this pigment possessed but little pigmentation, whereas those of the reciprocal crosses were strongly pigmented.

On breeding the F₁ birds together there resulted chicks of various grades of pigmentation, ranging from the deepest pigment to none at all. The F₂ generation, however, presented certain distinctions according as a pigmented or non-pigmented F₁ hen was used. When the F₁ female was crossed with the Brown Leghorn male none of the offspring was deeply pigmented, and this was true for the pigmented F₁ female as well as for the unpigmented. But when the F₁ male was crossed with a Brown Leghorn female about 1 in 8 of the offspring was deeply pigmented, and these were always females. Apparently there was a pigmentation factor, an inhibition factor, and a sex factor.

The Brown Leghorn male was homozygous for the inhibiting factor, and the female is, according to the hypothesis of the authors, always heterozygous for this factor. Because of certain exceptions to these results the authors are inclined to think that upon occasion the repulsion between factors may be imperfect, though it is not known whether this imperfection is sporadic or a part of some orderly scheme.

A Silky male was mated to a white Rosecomb bantam, and the results show that although the strain of Brown Leghorns was homogeneous in respect to the factor modifying pigmentation, yet its behavior with regard to the Silky pigmentation was not necessarily typical of breeds with unpigmented shanks.
On the inheritance of the webfoot character in pigeons, J. L. Bonhote (Proc. Zool. Soc. London, 1911, l, pp. 14-19, figs. 2).—A report of work which confirms the results of others that the webfoot behaved as a Mendelian recessive, but in which the normal course of Mendelian inheritance was distorted when two strains of webfeet were mated, although each strain by itself bred true. "We must, therefore, be driven back to the suggestion that a factor composed of two parts (cryptomeres), one of which is contained in each strain, causes the web to be suppressed or concealed."

[Experiments in pheasant breeding], R. H. Thomas (Proc. Zool. Soc. London, 1911, l, pp. 6-9).—Thaumalca obscura appeared to be a hybrid recessive mutation, breeding true, and was produced by crossing T. anhersti and T. picta. "By whatever name it is called, this hybrid is undoubtedly a homozygote for pattern and color, pure and permanent, transmitting these characters to its descendants. Cross-breeding between these two varieties of Thaumalca produces a new form, owing possibly to the meeting of characters never previously combined, and as they are constant it is evident these have an affinity and have become inseparable.

"On such lines evolution might be conceived as having proceeded fairly rapidly towards the separation of species."

Heredity and evolution, L. Plate (In Festschrift Richard Hertwig. Jena, 1910, vol. 2, pp. 535-610, pl. 1, figs. 3; abs. in Jour. Roy. Micros. Soc. [London], 1911, No. 4, p. 453).—Breeding experiments with mice led the author to have complete confidence in the Mendelian theory of the purity of gametes, and he maintains that Mendelism does not lessen the importance of selection, the conception of determinants being quite consistent with the transmission of acquired characters. Seven different modes of germinal variation and five kinds of atavism are given in an analysis of correlation. The author "proposes to modify Bateson’s ‘presence and absence’ theory into a ‘grundfaktor supplement-theorie.’"

Evolution, P. Geddes and J. A. Thomson (London, [1911], pp. 256).—A resumé of the evidence of the evolution of species as gathered from the study of variation, heredity, embryology, and palentology.

Bibliographia evolutionis (Bull. Sci. France et Belg., 41 (1910), Bibliogr. Évolutions, 1 (1910), pp. 162).—This is a bibliography of current works on heredity, variation, general cytology, experimental biology, and related topics, with abstracts of each noted. It is appended to each number of the journal, with separate pagination.

Commercial feeding stuffs, W. J. Jones, Jr., F. D. Fuller, and C. Cutler (Indiana Sta. Bul. 152, pp. 167-403, fig. 1).—This contains a summary of the state feeding stuffs law, rulings made under it, a classification of feeding stuffs, and similar data. Analyses are reported of 2,533 samples of feeding stuffs, including the by-products of wheat, rye, buckwheat, corn, flax, oats, and cottonseed; distillers' grains, brewers' grains, sugar beet pulp, alfalfa products, animal by-products, and condimental, poultry, and mixed feeds.

Botanical analyses were made of many of these feeding stuffs in order to determine the admixture of weeds and other foreign substances.

Preservation of beet pulp by the lactic ferment, L. Malpeaux (Betterave, 20 (1910), No. 516, pp. 310–314; abs. in Jour. Soc. Chem. Indias., 30 (1911), No. 15, pp. 971, 972).—When beet cossettes were inoculated with "lacto-pulp" it was found that there was but little difference in the composition from the uninoculated, there being only a slight loss in the amount of dry substance. The cellulose, carbohydrate, nitrogen, and ash content all decreased. The disagreeable odor sometimes given off by beet silage was suppressed by inoculation. When fed to lambs the preserved pulp gave satisfactory results.

Digestion experiments with bananas, M. Zagorodsky (Tropenpflanzer, Beilhette, 12 (1911), No. 4, pp. 327–341).—A report of digestion experiments conducted by Honcamp with 2 sheep, in which the basal ration consisted of clover hay and soy-bean meal.

The average coefficients of digestion were as follows: With banana meal, organic substance 75.9, dry matter 76.3, fat 106, and nitrogen-free extract 84.7; with banana peel meal, organic substance 66.9, dry matter 68.8, protein 34.1, fiber 22.1, fat 40.5, and nitrogen-free extract 80.1. Analyses are also given.

Report of work at Kodiak live stock and breeding station, M. D. Snodgrass (Alaska Stats, Rpt. 1910, pp. 63–65, pl. 1).—An account of progress made at the station in a study of the conditions affecting the rearing of live stock in Alaska along the lines noted in previous years.

The station herd of cattle at the time of the report consisted of 59 head of pure-bred Galloways and 10 cross-bred Galloway-Natives. During the year 40 head of Alaska-born grade ewes were purchased. They are a mixture of Cotswold, Shropshire, and other black-faced sheep, coming originally from the range sheep of the Northwest States and have proved well adapted to the climate. They are larger and longer woolled than is usually found on the ranges, and a more hardy sheep. The ewes sheared from 5 to 12 lbs. of wool per head, an average of 7.4 lbs. per head. The wool was of good quality and much cleaner than that from the ranges in the States, being practically free from sand and dirt. The sheep range for 11 months of the year and require very little feeding and shelter, except during the heaviest snowstorms.

Notes on hay making and the putting up of silage are also given.

Measurements of the experimental animals made from day to day show that the body of the pure-bred steer was longer at the start, but that after irregularities of the first 6 months both animals gained in length at a similar rate for the next 6 months, after which time the growth of the pure-bred steer was much less rapid than that of the scrub steer so that the former was finally overtaken. At the beginning of the experiment both steers were about the same height, but the scrub steer increased more rapidly than the pure bred and the rate of increase diminished in both animals as they grew older. The chest girth of the scrub was less than the pure bred at first, but its growth was in this respect more rapid for about 18 months. The increase in weight of the pure-bred steer was due much more largely than that of the scrub to an increase in size of the body. After slaughtering, the carcass of the pure bred was rated as prime and the scrub as common and there was a much higher percentage of dressed weight in the former and likewise the predominancy of the loin cut over the less valuable cuts of the forequarter as compared with the scrub. The scrub steer made relatively greater gains in live weight and required on the average a smaller amount of air-dried feed to produce a unit of gain, and a greater tendency toward gain of protein tissues than the pure bred.

Different amounts of hay were fed each year, one being slightly below the maintenance requirements and the other considerably below it, and designated maintenance and submaintenance rations, respectively, without implying that the former was an exact maintenance ration. The digestibility of the crude fiber of the hay was less in every instance, and that of the nitrogen-free extract in every case but one upon the heavier of the 2 rations, while the percentage of digestibility of the organic matter and total dry matter was less on the heavier ration. The same was true of the total carbon and total energy, but in 4 cases out of 6 the digestibility of the protein as here computed, assuming the nonprotein to be entirely digestible, was greater in the heavier ration, and the same was true of the total nitrogen, although the cases were not identical with those under protein. Ether extract in all cases showed a higher digestibility in the heavier rations.

The scrub consumed in every case relatively more hay, so it would be expected that any effect of the quantity of hay consumed would be to lower the digestibility, but the contrary was actually found to be the case the first 2 years, and this was true of the total dry matter, the organic matter, the crude fiber, the nitrogen-free extract, the carbon, and the energy with but a single exception—the energy of the submaintenance ration of 1905. In the third season the pure-bred steer seemed to have overtaken the other as regards the ability to digest hay, but the difference in every case was slight. The percentage of digestibility appeared to increase from year to year with both animals, the most striking difference being the notable increase in the digestibility of the nonnitrogenous ingredients in 1907 as compared with 1906.

In 1905 wheat bran constituted the exclusive grain ration; in the other 2 years the grain consisted of a mixture of bran, corn meal, and old-process linseed meal 1:3:3. The digestibility of the bran was greater on the heavier ration, with the exception of the ether extract, total carbon, and organic hydrogen in the case of the pure-bred steer, but the differences were small. With
the mixed grain feed the results were contradictory. There was but very little difference between the 2 animals.

In consequence of the relatively small losses in the feces observed in 1907, the total energy of the hay which was metabolizable was higher than in the two previous years, the averages for both animals being as follows: 1905, 40.11 per cent; 1906, 41.2 per cent; and 1907, 45.63 per cent, and the percentage of “digested” energy metabolizable, 1905, 79.93; 1906, 79.75; and 1907, 78.34 per cent. There was but very little apparent difference between the 2 animals as respects the percentage of energy metabolizable. The average results of the availability of metabolizable energy is shown in the following table:

<table>

The energy values of the feeding stuffs, technic employed, and method of feeding during intermediate periods are also given in detail.

Feeding experiments with beef cattle. R. S. Curtis (North Carolina Sta. Bul. 218, pp. 29-44, figs. 10).—The object of these experiments was to determine the difference in feeding value of corn stover, corn silage, and cotton-seed hulls when fed with cotton-seed meal. Western North Carolina steers, principally Shorthorn grades and weighing about 900 lbs., were used, and the same amount of cotton-seed meal was fed to each of the three lots. The feeds used were rated per ton as follows: Cotton-seed meal $30, cotton-seed hulls $8, corn silage $2.75, and corn stover $8. In figuring the profits manure produced was credited at $2 per ton.

Three lots of steers were fed for 112 days during the winter of 1909-10 an average of 8.14 lbs. cotton-seed meal per steer daily. In addition the steers in lot 1 were fed 16.52 lbs. corn stover and 23.17 lbs. corn silage; lot 2 was fed 35.36 lbs. corn silage; and lot 3, 17.92 lbs. cotton-seed hulls per steer daily. Lot 1 made an average daily gain of 1.31 lbs. at a cost of 17.94 cts. per pound and were fattened at a profit of $6.74 each. The corresponding figures for lot 2 are 1.35 lbs., 16.02 cts., and $9.20, and for lot 3, 1.43 lbs., 16.07 cts., and $8.58. These steers were bought at $4 and sold at $5.75 per hundred pounds live weight. During the winter of 1910-11 3 lots of steers were fed for 112 days an average of 6.77 lbs. cotton-seed meal daily per steer. In addition lot 1 received daily 20.8 lbs. corn stover and 23.64 lbs. corn silage; lot 2, 32.55 lbs. corn silage; and lot 3, 21.6 lbs. cotton-seed hulls. These steers cost $4.50 per hundred pounds. Lot 1 gained 1.3 lbs. daily at a cost of 17.17 cts. per pound, sold at $5.90, and made a profit of $1.90 each. Lot 2 gained 1.23 lbs. each daily, at a cost of 15.11 cts. per pound, sold at $6.00, and made a profit of $0.70 per steer. Lot 3 gained 1.45 lbs. each daily at a cost of 14.19 cts. per pound, sold at $5.725, and made a profit of 31 cts. per steer.

Though in each case the steers fed cotton-seed meal and hulls gained more than the other lots, the author states that the quality of the carcass was not as desirable, nor was the dressing percentage as high as that for the two lots receiving silage and stover. The statement is made that the high cost of gains
made by these steers was partially due to using a grade of steers inferior in
breeding and in gaining qualities, and that high-grade feeders properly fed
should make double these gains, reducing the cost one-half.

Feeding and management of beef cattle, R. S. Curtis (North Carolina Sta.
Bal. 219, pp. 51-68, figs. 11).—This is a popular account of the beef cattle
industry of North Carolina.

More care in the selection of feeding cattle is urged and, on account of the
large amount of cotton-seed meal usually fed under southern conditions, short
feeding periods ranging from 100 to 120 days are suggested. The use of corn
silage and other home-grown feeds is advocated. It is stated that the most sat-
sactory financial results are usually obtained by selling the finished cattle
at home, though shipping under certain conditions may prove advisable. Some
of the disorders incident to the finishing of beef cattle are noted.

Contribution to the physiology of the nutrition of growing animals.—
II, The utilization of the protein in milk by calves, G. Fingerling (Landw.
Vers. Stat. 74 (1910), No. 1-2, pp. 57-80).—Digestion experiments showed that
as the calves grew older they needed a smaller percentage of protein. When
given whole milk a large percentage of the protein was excreted. For eco-
nomical gains easily digested fats and carbohydrates should be added to the
milk after the first few weeks.

On the gain in protein in fattening full-grown wethers, T. Pfeiffer and
K. Friske (Landw. Vers. Stat., 74 (1911), No. 6, pp. 309-345).—Full-grown
wethers when fattened showed a gain in nitrogen in the form of flesh on both
wide and narrow rations, this gain being much faster when the animals had
previously been kept in a poor condition. As in a previous report (E. S. R., 22,
p. 473) the metabolism experiments indicated a higher gain in nitrogen than
did the slaughter tests, and this difference was greater on a narrow than on a
wide ration. Though most of the loss in nitrogen took place during the drying
of the feces, it is pointed out that probable further loss of nitrogen as ammonia
takes place from the lungs and skin and as gas in the intestinal canal.

Agr., 3 (1911), No. 2, p. 109).—Twenty wethers 12 weeks from shearing were
put on rape and allowed the run of a grass paddock adjoining. They made an
average gain in 12 weeks of 2.75 lbs. each more than a similar lot of unshorn
lambs.

Cirencester, 1910, No. 2, pp. 94-96).—A study of the twinning ability in pure-
bred Oxford Down sheep.

In 1909 12 pedigree Oxford Down twin theaves were purchased, 6 from mixed
twins and the other 6 from ewe twins. These were mated in 1910 and 1911
with a pedigree Oxford Down ram. Although the experimental flock is small,
the results for 2 years were as follows: All the twins were borne by ewes from
mixed twins; the twins were predominantly mixed, and there was no case of
ram twins; the ewes which were originated from mixed twins produced, taking
twins and singles together, twice as many ewe lambs as ram lambs; the ewes
from the ewe twins nearly all produced ram lambs.

The effect of food on the strength, size, and composition of the bones of
hogs, E. A. Burnett (Nebraska Sta. Rpt. 1910, pp. 178-208, figs. 3).—A report
of experiments in continuation of those already reported (E. S. R., 20, p. 868).

In a test with 41 pigs fed at the North Platte Substation in 1908-9, the
average breaking strength of all the bones tested (femur, tibia, humerus, and
radius and ulna), per 100 lbs. live weight, for the different lots was as follows:
On ground corn 465 lbs.; on ground corn and alfalfa meal 9:1, 397 lbs.; on
ground corn, alfalfa meal, and tankage, $85:10.5$, 489 lbs.; on ground corn, alfalfa meal, and bone meal $85:10.5$, 573 lbs.; and on ground corn, alfalfa meal, and shorts $75:10.15$, 470 lbs.

In a test with 14 pigs at the central station in 1909–10, the average figures for the different lots were as follows: On ground corn, 272 lbs.; ground corn, alfalfa meal, and bone meal $85.5:10.4.5$, 384 lbs.; on ground corn and alfalfa meal 9:1, with 1.5 per cent calcium carbonate for one month, 275 lbs.; on ground corn, alfalfa meal, and crystallized disodium phosphate, $86.6:10.3.4$, 301 lbs.; and on ground corn, alfalfa meal, and tankage $85.5:10.4.5$ per cent, 276 lbs.

The wall thickness, the percentage of mineral matter, and, except with the corn-fed lot in 1908–9, the specific gravity varied with the breaking strength. The relation of length, circumference, and volume to the breaking strength was not well marked.

"In both tests the weakest bones were those from the hogs fed corn only. The addition of alfalfa meal slightly increased the strength. The further addition of shorts gave a noticeable increase, while the addition of tankage and especially of bone meal gave a very marked increase."

Swine breeding. F. Hoescu (Die Schweinezucht. Hanover, 1911, vol. 1, pp. XIII+476, figs. 113).—The first volume of this work treats of the natural history of the Suidae, the domestication of different species by man, and the origin and character of the modern breeds of swine.

Training farm for elephants in the Belgian Congo; their utilization in agriculture. Devèdeix (Jour. Agr. Prot., n. scr., 21 (1911), No. 12, p. 369, fig. 1; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Discoues. 2 (1911), No. 4, p. 906).—A description of the farm and methods practiced. By making use of the elephant it has been possible to plow vast tracts of land which were formerly unproductive.

Zebras as transport animals (Agr. Jour. Union So. Africa, 2 (1911), No. 2, pp. 144, 155).—Experience with zebras as draft animals showed that they pull steadily and respond quickly to the whip. They kept in good condition without corn feeding and appeared more intelligent than mules or donkeys. Although experience so far indicates that they lack in stamina, this is thought to be due in part to the manner of feeding.

Mustard for poultry? Report of an experiment conducted at Llangam-march Wells poultry farm, 1909–10, R. R. Allen (Saucebridgeworth, England, 1911. 2. ed., pp. 27); abs. Jour. Nat. Poultry Organ. Soc., 5 (1911), No. 1, p. 49).—Hens fed upon mustard during the winter season produced a much larger number of eggs than without any stimulant, or those which received capsicum as a stimulant. During the warm months the reverse was true, but taking the year as a whole the results for 6 pullets of Buff Orpingtons in each lot were as follows: Ordinary food, 914 eggs; capsicum as a stimulant, 905 eggs; mustard as a stimulant, 1,023 eggs.

Further experiments are contemplated.

The Plymouth Rocks, edited by W. C. Denny (Quincy, Ill. and Buffalo, N. Y., 1911, pp. 128, pls. 3. figs. 118).—A series of articles by different authors on the history of the breed, origin of different varieties, and other information regarding the Plymouth Rock fowls.

The Rhode Island Reds, edited by D. E. Hale (Quincy, Ill. and Buffalo, N. Y., 1911. pp. 86, pl. 1, figs. 76).—The origin and characteristics of standard types and how to mate a bird for the best results are discussed in a series of articles by different authors.

Plant Diseases, 2 (1911), No. 4, p. 915).—A brief description of this breed, which is common in Austria, Hungary, and the Balkan States.

Maine experiments with cross-bred poultry, J. H. Robinson (Farm Poultry, 22 (1911), Nos. 8, pp. 206-208; 9, pp. 222-224).—A review of work previously noted (E. S. R., 23, p. 674).

On the structure and function of the oviduct of the pigeon, B. Hankó (Allattani Kézelm., 9 (1910), No. 1, pp. 26-48; abs. in Zentbl. Allg. u. Expt. Biol., 2 (1911), No. 7-8, p. 290).—This describes the histology of the oviduct and the physiology of the secretions connected with it. In general there were but slight differences from those previously reported by other observers from studies of the domestic fowl.

Oviposition induced by the male in pigeons, W. Craig (Jour. Morph., 22 (1911), No. 2, pp. 299-305).—It was found that pigeons differ from fowls as the male stimulates the female to lay without copulation. In one case stimulation by the hand of man was followed by oviposition. Old females, if kept isolated, refrained from laying. It is concluded that the stimulus to the whole process of egg laying is a psychic stimulant and not dependent upon copulation.

DAIRY FARMING—DAIRYING.

Care and management of the dairy herd, J. C. McNutt (North Carolina Sta. Bul. 220, pp. 73-84, figs. 9).—A popular bulletin dealing with the selection, feeding, and improvement of dairy cows under North Carolina conditions. The feeding of corn silage and other home-grown feeds is urged. The care and management of the herd bull, raising of dairy calves, and the age to breed heifers are discussed.

[Report of dairy work], G. H. True (Nevada Sta. Bul. 73½, pp. 36-38).—The yearly records of the cows of the station herd and the best 7-day records are given. In a dairy survey of Douglas County the average production of milk fat in 54 herds was found to be 221.48 lbs. per year, the range being from 91.8 to 317.75 lbs.

A breeder’s herd records, G. Harold (Country Gent., 76 (1911), No. 3059, p. 10, figs. 4).—Illustrations are given of methods of keeping milk and breeding records on a dairy farm.

Milk tests (Field Expts. Harper-Adams Agr. Col., and Staffordshire and Shropshire, Rpt. 1910, p. 53).—The average percentage of fat in the milk of the college herd was 3.5 in the morning and 4.04 in the evening milk. The average yield of cheese per gallon of milk was 1.26 lbs. The lowest yield was 1.08 lbs., occurring in June, and the highest 1.48 lbs. in February.

An experimental study of the causes which produce the growth of the mammary gland, R. T. Frank and A. Unger (Proc. N. Y. Path. Soc., u. ser., 11 (1911), No. 1-2, pp. 4-8).—To ascertain whether heterologous fetal extracts produced breast hyperplasia, rats were injected with cow’s fetuses, rat’s fetuses, ovaries, and placentas. Starling’s technic was employed, but the results were negative. The same methods were then used with rabbits, using extracts of rabbit’s fetuses, ovaries, placentas, and hypophyses. The results varied greatly
and showed no correspondence to the tissues used for injection, so that the authors were forced to conclude that there was some unknown factor yet to be accounted for.

Can the fat content of milk be increased by the feed? P. Wauters (Lait, et Elevage, 6 (1911), Nos. 4, pp. 29-31; 3, pp. 35-37; abs. in Internat. Inst. Agr. [Rome], Bull. Bur. Agr. Intl. and Plant Diseases, 2 (1911), No. 4, p. 83).—The author’s experience for 20 years with a herd of cows led to the conclusion that the diet of the cow has but very little influence on the composition of the milk, although in France the overfeeding of milch cows with watery feeds has been condemned as a fraudulent practice because it is thought to contribute to the deterioration of the milk.

The properties of colostrai fat, S. Engel and A. Rode (Ztschr. Physiol. Chem., 74 (1911), No. 2, pp. 169-174).—The chemical constants of the colostral fats of several cows were determined from day to day during the period immediately following parturition, with a view to noting the changes from colostral fat to normal milk fat.

The iodin number gradually decreased from day to day. The saponification number remained low for 2 or 3 days, but was gradually raised throughout the period as a whole. The Reichert—Meissel number was more or less irregular, but up to about the fifth day there was an increase and then a slight decrease. The determination of similar constants of goat colostrum showed considerable irregularity.

Bacteria in milk produced under varying conditions, W. K. Brainerd (Virginia Sta. Rpts. 1909-10, pp. 65-77).—This is a detailed account of work already reported (E. S. R., 23, p. 581).

Milk with a soapy taste, O. Fettick (Ztschr. Fleisch u. Milchhyg., 21 (1911), No. 12, pp. 389-392).—A bacillus 0.82 to 1.5 microns long and 0.3 to 0.5 microns in thickness was found to be the cause of a soapy taste in milk. In pure cultures they formed round, yellowish-brown colonies. The trouble was removed by disinfecting the stable and thoroughly cleansing the milk utensils.

Report on the chemical changes produced in milk by bacteria and their relation to the epidemic diarrhea of infants, H. A. Schoelberg and R. L. M. Wallis (Ann. Rpt. Local Gort. Bd. [Gt. Brit.], 39 (1909-10), pp. 501-543; abs. in Jour. Chem. Soc. [London], 106 (1911), No. 584, II, p. 512).—In the summer months peptones appeared in fresh samples of milk, the quantity of albumoses and peptones depending upon the age of the milk and on the temperature at which it has been kept. Incubation of milk for from 15 to 24 hours at 37° led to the production of peptones, although longer periods of incubation caused it to disappear. Investigations on the pancreas of infants showed a toxic effect of peptones and the peptone-like substances which were formed by a large number of both sporing and nonsporing varieties. Some of the organisms isolated produced a substance which can replace secretin in pancreatic digestion experiments.

Report upon the bacterial measurement of milk pollution, W. G. Savage (Ann. Rpt. Local Gort. Bd. [Gt. Brit.], 39 (1909-10), pp. 474-503).—There was a general agreement between cleanliness in cows’ stables and the number of bacteria, so that with a uniform method of determining the bacterial content unsanitary stables and unclean methods of milking should be easily detected by bacterial enumerations.

A study of the influence of time and the temperature at which the milk was kept showed great irregularities in rate of increase of bacterial growth when the milk was kept at 15 and 21° C, but the increase was always faster at the higher temperature. Temperature was found to be a more important factor
than the initial number of bacteria in determining the final number of *Bacillus coli*, but both were important. From the few experiments made it seems that time is less important than temperature.

The results of 24 hours' incubation at 15° were similar to those of the same samples after railway transmission, and it is stated that a standard of not more than 1,000 *coli* and allied organisms per cubic centimeter of milk is reasonably practicable. Experiments also showed very clearly the immense importance of thorough initial cooling of the milk before transportation.

The number of the spores of *B. enteritidis sporogenes* was determined in over 50 samples of fresh milk, and showed a considerable agreement with the number of *B. coli*.

Four experiments were carried out to study the bacterial changes caused by milk filtration, and on the whole no advantage from a bacteriological standpoint was obtained by filtering, although one of the supposed best strainers was employed, the apparatus steamed before each experiment, and the wool used for the filtration of only half a gallon of milk. In an examination of the centrifugalized deposit only 5 out of 50 fresh milk samples were found to contain streptococcus chains, and in only 2 were they present in any numbers. They were present in only a few of the incubated milk deposits.

There was no increase at the end of 24 hours in the acidity of fresh samples of milk incubated at 15°, and in some instances there was an actual decrease of their acidity. Samples incubated at from 20 to 21° showed more frequently an increase, but even at this temperature it was often absent.

A trial of the Schardinger test gave results that were not uniform, but on the whole there was a relation between the reduction time and the freshness of the milk.

No high value was placed on examining incubated milk as to acidity and clotting. If a milk clotted after 6 hours of incubation at 37°, either spontaneously or on heating, the limited tests made showed that at the time of sampling it was bacteriologically unsatisfactory, but the absence of clotting was not any evidence of initial purity.

Some of the general conclusions reached were as follows: The estimation of the number of *B. coli* and allied lactose ferments, the estimation of the spores of *B. enteritidis sporogenes*, and the examination of the stained deposit, are all processes of considerable value in forming a reliable judgment as to the bacterial pollution of milk. The use of milk strainers is discouraged for the following reasons: "They are useless to improve the bacterial quality of the milk; unless great care is taken to keep them scrupulously clean they frequently actually increase the number of bacteria in milk; they encourage the farmer to think that cleanliness precautions can be neglected or at least relegated to a secondary place, since all additions are removed by the strainer. This view has again and again been presented to me by the farmer as an excuse for want of cleanliness in milking."

On the virulence of the lactic ferments contained in the excrements of milch cows, C. Gorini (Read. R. Ist. Lombardo Sci. e Let., 2. ser., 43 (1910), No. 18, pp. 777-789; abs. in Internat. Inst. Agr. (Rome), Bul. Bur. Agr. Intl. and Plant Diseases, 2 (1911), No. 2, p. 363; Milchew. Zentbl., 7 (1911), No. 9, pp. 426-429.—The author isolated several strains of lactic-acid bacteria obtained from the feces of cows in dairies at high altitudes. They possessed such an extraordinary activity that it is thought they should prove valuable as starters, either to hasten the process of ripening or to overcome undesirable species when present.

The score card system of dairy inspection from the national standpoint, G. M. Whitaker (Jour. Amer. Pub. Health Assoc., 1 (1911), No. 9, pp. 647-
A report of progress as to the score card system of inspecting dairies, and its significance in promoting the health of the community by encouraging the production of sanitary milk.

Cooperation for the protection of milk supplies, C. W. Eddy (Mo. Bul. Ohio Bd. Health, 1 (1911), No. 9, pp. 298-304).—The purpose of this paper is to point out the vital necessity of cooperation between organized communities in safeguarding the milk supply, so that milk refused by one city for failure to meet its requirements will also be refused by others. When this is not the case the milkman whose milk is rejected may sell the same product elsewhere.

[Results of milk inspection] (Rpt. Dept. Health Chicago, 1907-1910, pp. 260-285, figs. 3).—This article contains data on the relative toxicity of raw and pasteurized milks and reports efficiency tests of the different types of pasteurizers. A filtration test of visible dirt in milk is illustrated and described.

Pasteurization of milk in the sealed and final package, J. C. Carter (Jour. Amer. Pub. Health Assoc., 1 (1911), No. 9, pp. 664-668).—A method is described for pasteurizing milk after it has been put into sealed bottles. The bacterial content was only from about 800 to 6,000 per cubic centimeter when delivered to city customers.

Sterilizing stations in dairy districts, C. E. North (Jour. Amer. Pub. Health Assoc., 1 (1911), No. 9, pp. 654-663).—An account of how a dealer obtained a cleaner milk by offering an extra price of ½ ct. per quart for milk with a low bacterial content. It also cost him 1 ct. per quart to operate a sterilizing station where 4,000 qts. per day were handled, making the total cost 1½ cts. per quart over that of milk shipped in the ordinary way.

The improvement of milk transportation, C. Clément (Lait. et Élevage, 6 (1911), No. 8, pp. 57-60; abs. in Internat. Inst. Agr. (Rome), Bul. Bur. Agr. Intel. and Plant Diseases, 2 (1911), No. 4, pp. 908, 909).—Estimates are given on the cost of transporting milk in Belgium and Prussia, with a view to its reduction. On a consignment of 480 bottles of 125 gm. in pigeon-hole boxes, sent by freight to a distance of 50 km. (31 miles), the charge was 3.4 francs (65.8 cts.) in Belgium, including the return of the boxes with the empty bottles, while the same service in Prussia cost 1.5 francs. A consignment of 128 bottles of 1 liter, sent under the same conditions, cost 3.6 francs in Belgium and 2.25 francs in Prussia.

Does the iron in water affect the quality of butter? W. D. Kooper (Milch Ztg., 40 (1911), No. 29, pp. 285-287).—Water containing 36 mg. of iron per 1,000 cc. when added to cream before churning and working produced no off flavor in butter, but when added to sour cream and allowed to stand some time a metallic taste resulted, this being more pronounced in a cream of high acidity. It is pointed out that when other substances which unite readily with iron are present compounds will be formed which produce the metallic taste.

Taylor absorption process for making butter, C. W. Larson (Pennsylvania Sta. Rpt. 1910, pp. 158-159, pl. 1).—A report of an experiment in butter making by a patented process, which consists in removing the proteids and sugar which are in solution in the cream by means of an absorption pad instead of a churn. The resulting product, which is rich in milk fat, remains on a separating pad and can be eaten sweet or worked and salted as ordinary butter. "The sweet cream layer as removed from the pan resembled sweet, unsalted butter, but was not as firm in texture as well-made churned butter. The kneaded and salted product when made from ripened cream has the appearance of butter. The flavor was good or bad, depending upon the flavor of the cream used." Analyses of 6 samples of the product showed great variation in all of the constituents.
The following conclusions are drawn: "That with the absorption process a product that resembles butter in flavor, texture and composition can be produced; that where a small amount of a sweet cream product, high in butter fat, is desired, this apparatus may meet a demand: that for producing butter in a commercial way the apparatus used in these tests does not furnish a substitute for the churn; that the product cannot be classed as butter under the United States standards of moisture and fat."

Studies of Bitto cheese, G. Fascetti (Riv. Sci. Latte, 1 (1911), No. 1, pp. 1-12).—This cheese, which takes its name from the Valley of the Bitto, a tributary of the Adda, is made principally in 2 types similar to Battelmatt, a fat, soft cheese with holes like Gruyère, weighing from 20 to 25 kg., and Shirnuz or Spalen, a semi-fat cheese weighing from 10 to 30 kg. Originally Bitto was made of four-fifths cow’s milk and one-fifth goat’s milk. The annual product amounts to about 3,000 quintals (about 330 tons), some of which is consumed fresh and the rest allowed to ripen for a year or two. The texture of the cheese is smooth and the holes, which are 2 to 3 mm. in diameter, are regularly distributed. When 2 years old the cheese is hard, of strong flavor, and the holes become filled with a dense liquid of a pleasant taste. Analyses of 4 samples of Bitto cheese gave the following percentages: Water 31.78, fat 33.59, casein 28.81, and ash 4.83.

The use of steam in the manufacture of Parmesan cheese, A. Oliva (Avicen. Agr., 19 (1911), No. 3, pp. 106-111; abs. in Internat. Inst. Agr. [Rome], Bull. Bur. Agr. Intl. and Plant Diseases, 2 (1911), No. 4, pp. 910, 911).—Estimates are given of the comparative cost of heating cheese milk directly by wood fire and by steam. The difference in cost between the two methods is very slight, but the steam installation will also furnish power for churning and gives a larger yield of butter of more even grain than hand labor.

Composition of dried milk powders, A. Burh (Militär. Zentbl., 7 (1911), No. 3, pp. 118-133; abs. in Analyst, 36 (1911), No. 423, p. 279).—Analyses are reported of cream powder, full-milk powder, skim-milk powder, and whey powder.

How to use the Babcock test, J. L. Sammis (Wisconsin Sta. Circ. Inform. 27, pp. 26, figs. 19).—Directions are given for testing milk, skim milk, buttermilk, whey, and cream on the farm. A form of milk record sheet is illustrated, and methods of calibration of Babcock glassware are given. Rules for calculating dividends by the fat test in creameries are outlined, and several practical problems in calculating milk and cream tests are appended.

VETERINARY MEDICINE.

Report of the veterinary director general and live stock commissioner, J. G. Rutherford et al. (Rpt. Vet. Dir. Gen. Canada, 1909, pp. 212, pls. 26, charts 36).—This report for the year ended March 31, 1909, includes 19 appendixes. Among the more important contributions presented are the report of the pathologist, by C. H. Higgins (pp. 58-69); dourine (pp. 70-72), loco-disease (pp. 74-80), the life history of Trypanosoma equiperdum (pp. 90-92), and a contribution on sarcosporidiosis with special reference to its associations with loco-disease and dourine, and the possibility of mistaking the spores of Sarcocystis for certain so-called developmental forms of trypanosomes (pp. 93-100), by E. A. Watson; redwater investigations in British Columbia (pp. 101-112), by T. Bowhill; and open air experiments with tuberculous cattle (pp. 169-188), by J. G. Rutherford.

the more important contributions presented are the report of the pathologist (pp. 53–57), by C. H. Higgins; a further investigation of parasites (pp. 57–59), by S. Hadwen; experimental studies of dourine (pp. 60–93), by E. A. Watson, assistant pathologist; and an account of rabies (pp. 96–103), by G. Hilton, chief veterinary inspector.

**Activities of the institute of animal hygiene at Freiburg in Baden, 1909** (Mitt. Ver. Rad. Tierärztl. 10 (1910), Nos. 4, pp. 49–54; 5, pp. 65–73; abs. in Centbl. Bakt. [etc.], 1. Abt., Rcf., 49 (1911). No. 5, pp. 129–131).—This extensive report deals with vaccination against hog erysipelas, mallein tests, pathological-anatomical examination of material sent in for diagnosis, and discussions of the findings. During the period under report, 1,255 mouse typhoid and 1,026 rat plague cultures were sent out.

**Meat and its inspection, A. R. Litteljohn** (London, 1911, pp. XII+399, figs. 33).—A practical guide for meat inspectors, students, and health officials.

The toxic action of the products of tryptic digestion and anaphylaxis, O. Hartoch and N. Sirenskij (Ztschr. Immunitätstsf. u. Expt. Ther., I. Orig., 7 (1910), No. 3, pp. 253–273).—The results show that by tryptic digestion of proteins toxic bodies are formed which when injected into a guinea pig produce the classical symptoms of anaphylaxis. The toxicity of the products becomes greater the longer the tryptic digestion process is continued. According to the authors these findings seem to prove that anaphylaxis is the result of poisoning with intermediary cleavage products of proteins.

**Influence of quinin and morphia upon phagocytosis, II. L. Smith** (Lancet [London], 1910, II, No. 19, p. 133; abs. in Jour. Amer. Med. Assoc., 55 (1910), No. 23, p. 2018).—Moderate doses of quinin and morphin stimulate phagocytosis, while large amounts diminish it.

**Scarlet red ointment in veterinary practice, Kösters** (Ztschr. Veterinärk., 23 (1911), No. 4, pp. 198, 199; abs. in München. TierärztL. Wchnschr., 55 (1911), No. 29, p. 589).—Large and small wound areas which were treated at first with a 5 per cent and later with an 8 per cent scarlet red ointment quickly granulated. The author points out that in order to be successful with this form of treatment, which is inexpensive, it is necessary to have a clean (nonpurulent) granulating surface.

**Remedies for animal parasites, W. H. Schultz** (Jour. Amer. Med. Assoc., 57 (1911), No. 14, pp. 1102–1106).—A study of the relative efficiency and danger of thymol as compared with certain other remedies proposed for hookworm disease.

The rôle of the infective granule in certain protozoal diseases, A. Balfour (Jour. Trop. Med. and Hyg. [London], 14 (1911), No. 17, pp. 263, 264).—“In spirochetosis and trypanosomiasis, what may be called the infective granule probably plays an important rôle. It marks a stage in the life cycle of the parasite, explains in some measure latent infections and possible relapses, and serves to clear up the obscure mechanism of relapses.” It is stated that Fry has shown that both Trypanosoma brucei and T. evansi shed living granules. These become plasmodial masses out of which eventually trypanosomes are developed. The granules are thought to be of a spore nature; they are resistant and not easily stained by the Romanowsky process. (See E. S. R., 25, p. 788.)

**Observations on the occurrence in the blood of various animals (chiefly monotremes and marsupials) of bodies apparently identical with Anaplasma marginale, Theiler, 1910, J. A. Gilruth, Georgia Sweet, and S. Dodd** (Parasitology, 4 (1911), No. 1, pp. 1–6, pl. 1).—The authors, who have conducted investigations at the Veterinary Institute, Melbourne University, report the discovery of bodies, apparently identical with A. marginale, in the blood of the
common pig and 10 species of native animals. They are inclined to the belief that, at least so far as these indigenous forms of mammals are concerned, the presence of these bodies, though possibly parasitic in nature, has no pathological significance.

Concerning Anaplasma marginale.—A contribution to the knowledge of Texas fever and "galziekte," H. Sieber (Berlin. Tierärztl. Wochenschr., 26 (1910), No. 50, pp. 993-998, figs. 6; abs. in Jour. Comp. Path. and Ther., 24 (1911), pp. 146, 147).—The author, after briefly reviewing the literature on the subject, describes the course of the disease in 2 animals experimentally infected, one of which terminated fatally.

Transmission of amakebe by means of Rhipicephalus appendiculatus, the brown tick, A. Theiler (Proc. Roy. Soc. London, Ser. B, 84 (1911), No. B. 569, pp. 112-115).—The author finds that amakebe of Uganda is identical with East Coast fever of South Africa and that it is transmitted by R. appendiculatus, which is common in Uganda.

The capybara as a reservoir for the virus of mal de caderas, L. E. Micone (Bul. Soc. Path. Exot., 3 (1910), No. 8, pp. 521, 525; abs. in Sleeping Sickness Bür. [London] Bul., 2 (1910), No. 22, p. 413).—In Paraguayan epidemics of mal de caderas in horses are frequently preceded by an excessive mortality of the carpincho, or capybara (Hydrochoerus capibara), a large rodent which frequents the water. In a previous account, Elmassian and the author reported an epidemic among dogs that had hunted and eaten capybaras (E. S. R., 16, p. 716). In an investigation conducted by the author during the course of an epizootic among capybaras in April, 1910, in which paralysis of the hind-quarters was the predominant symptom, trypanosomes were found in their blood for the first time. Monkeys (Victipithicus felinus) injected with blood from capybaras showed trypanosomes on the fifth day and died on the seventeenth day, with the same symptoms as observed in the capybaras. The manner of conveyance of the infection from capybaras to horses was not determined.

Hematological studies of dogs experimentally infected with surra, A. Lanfranchi (Clin. Vct. [Milan], Sez. Sci., 33 (1910), No. 4-6, pp. 218-240; abs. in Sleeping Sickness Bür. [London] Bul., 2 (1910), No. 21, pp. 376, 377).—Studies of the blood of dogs experimentally infected with Trypanosoma evansi are reported. A bibliography of 23 titles is appended to the account.

On the occurrence of an intracellular stage in the development of Trypanosoma lewisi in the rat flea, E. A. Minchin and J. D. Thomson (Brit. Med. Jour., 1911, No. 2632, pp. 361-364).—A preliminary note, in which the authors report having found that in the early phases of the developmental cycle the rat trypanosome penetrates into the cells of the epithelium lining of the stomach (midgut) of the flea, and there goes through a process of multiplication.

The coyote as a host of Multiceps multiceps, M. C. Hall (Abs. in Science, n. ser., 33 (1911), No. 860, pp. 975, 976).—In order to determine whether the coyote carries the adult gid tapeworm, the larval M. multiceps obtained from the brain of a giddy sheep was fed on April 4, 1911, to 2 coyotes. Each animal receiving about one-half of the cyst.

"One coyote was found dead the morning of April 10. Post-mortem examination showed death to be due to septicemia. The entire length of the small intestine showed severe ecchymotic hemorrhage. Fifty-two heads of M. multiceps were recovered from the intestinal contents. A comparison of these worms after 6 days' development with some recovered from a dog after 10 days' development shows the worms had established themselves and were developing normally. They were still very small but there is no reason to suppose that they would not have developed to maturity if the coyote had lived."
"The coyotes, *Canis nebraccensis*, . . . were obtained in northern Montana in the area where gid is enzootic and the coyote, therefore, must be considered, in view of the experimental findings, as sharing with the dog the responsibility for carrying the gid parasite and maintaining the gid disease in that State."

A third case of *M. serialis* in the squirrel is also noted, the author having produced the larval *M. serialis* in an American squirrel, *Sciurus carolinensis*, by feeding proglottides of the adult worm from the dog.

The diagnosis of anthrax with the precipitation method, W. Pfeiler (*Berl. Tierärztl. Wchnschr.*, 27 (1911), No. 13, pp. 217, 218).—The author was able to confirm Bierbaum’s conclusions (E. S. R., 25, p. 782) that anthrax can be diagnosed in putrefied material with the precipitation reaction.

Investigations in regard to the bacteriological detection of the anthrax bacillus in cadavers and parts of cadavers, H. Foth and Wulff (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 8 (1910), No. 1, pp. 15–38).—None of the well-known methods for detecting anthrax bacilli, according to the authors, can be absolutely relied upon for detecting anthrax in dead animals if the examination is not begun very soon after death.

The bacterioscopic test with blood preparations is the best. Gypsum rods when prepared according to various methods yield differing results. (See also above.)

The diagnosis of symptomatic anthrax, I, H. Foth (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 8 (1910), No. 2–3, pp. 117–139, pls. 7).—Continuing previous work (E. S. R., 23, pp. 584) the author points out that symptomatic anthrax is a septicemia, and furthermore that the causative organisms may be distributed throughout the entire animal body. The bacilli can usually be detected by bacteriological methods, but if the cases are recent it may be necessary to use enriching methods. In this connection the author points out that in some instances in animals dying from other diseases a bacillus is often present which simulates the causative organism of symptomatic anthrax. The morphological and biological characteristics of the organism are given in detail.

[Report on anthrax], C. Ponder (*A Report to the Worshipful Company of Leathersellers*. London, 1911, pp. VI+88, fig. 1, qms. 3).—This is a detailed report in regard to anthrax, and of inquiry into certain measures aiming at its prevention.

Among the topics reported are anthrax in animals, the collection, curing, and shipment of hides and skins, anthrax and the tannery, the incidence of anthrax among those engaged in the hide, skin, and leather industries, and the prevention of industrial anthrax. Appendixes deal with the preparation of test materials containing anthrax spores, the reaction of calcium hydroxid (the liming process) on anthrax spores, and the Seymour-Jones formic-mercury process.

Strangles, A. G. Todd (*Jour. Comp. Path. and Ther.*, 23 (1910), No. 3, pp. 212–229, qms. 1; abs. in Centbl. Bakter. [etc.], 1. Abt., Ref., 39 (1911), No. 5, p. 131).—The author discusses the pathology, symptoms, preventive measures, and immunizing tests conducted up to the present time, and in connection with these he reports the results obtained by himself with a vaccine which he terms Strangline.

The vaccine used was prepared from streptococci isolated from cases of strangles, and which were passed through a mouse and cultivated further on blood serum. The cultures so obtained were then propagated for one month in flasks containing 500 cc. of 10 per cent serum-bouillon at 37° C. After this time had elapsed, 6 per cent of glycerin was added to the culture and the flask kept for 2 days over unslaked lime at 60°. This process killed the streptococci and congealed the contents of the flask. To the congealed mass sterile
water containing 0.5 per cent of carboxyl acid was added to bring the bouillon back to one-half of the original volume. The vaccine thus prepared was given subcutaneously in doses of from 1 to 10 cc.; the results obtained were considered good.

**Treatments of tetanus during the period of contraction,** J. Camus (Compl. Rend. Soc. Biol. [Paris], 68 (1910), No. 10, pp. 160–163; abs. in Zentbl. Biochem. u. Biophys., 10 (1910), No. 4, p. 187).—Dogs were injected with tetanus toxin and divided into three groups. One group received tetanus antitoxin and guinea pig brain emulsion, a second tetanus antitoxin alone, and the third brain emulsion alone in the spinal fluid. Those receiving tetanus antitoxin plus brain emulsion recovered but the other two groups did not.

**Final report of the royal commission appointed to inquire into the relations of human and animal tuberculosis** (Roy. Com. Tuberculosis, Final Rpt., 1911, pt. 1, pp. IV+54).—The original questions propounded to the commission were the following: “(1) Whether the disease in animals and man is one and the same; (2) whether animals and man can be reciprocally infected with it; (3) under what conditions, if at all, the transmission of the disease from animals to man takes place, and what are the circumstances favorable or unfavorable to such transmission.” The animals used in the investigations were cattle, rabbits, guinea pigs, goats, chimpanzees, monkeys, horses, cats, mice, rats, dogs, and birds. The bacilli used for the infection and cultural tests were obtained from the lesions of the natural disease.

In regard to the first question the commission points out that the human and bovine type of bacilli are morphologically indistinguishable, but are somewhat different in regard to their cultural characteristics and their capacity for producing the disease in various species of animals, so that the diagnosis “clearly depends upon the importance which it is permissible to attach to their cultural and pathogenic differences, and this in turn on the fixity or variability of the differences in question.” The human type of bacillus was found to produce a fatal tuberculosis in guinea pigs, chimpanzees, and monkeys. But caused only slight and nonprogressive lesions in cattle, goats, and pigs. Guinea pigs, monkeys, and chimpanzees were also highly susceptible to the bovine type of bacillus, but the type of disease produced by this bacillus was anatomically and histologically identical with that produced by the human type of bacillus. Experiments with the bovine type of bacillus in man were not conducted, but comparisons with cases probably caused by the bovine type of bacillus were made.

“Except for the difference in the type of bacillus found in the 2 groups of cases presented [the cases themselves had] similar features; the clinical histories of the patients were alike, the cases all terminated fatally, and the lesions examined after death were found to be anatomically indistinguishable. Man must therefore be added to the list of animals notably susceptible to bovine tubercle bacilli.” Attempts to transmute the bovine type into the human type, or vice versa, in most instances failed, from which the commission concludes that it is a very difficult thing to produce such transmutations under ordinary laboratory conditions. There is, however, “an aspect in which tuberculosis in men and in cattle must unquestionably be pronounced one and the same disease. Whether one prefers to regard bovine tuberculosis and the cases of tuberculosis in man which are caused by the human type of bacillus as varieties of the same disease or as independent diseases, there can be no question that human tuberculosis is in part identical with bovine tuberculosis.” No conclusion was drawn in regard to whether avian tuberculosis, when compared with either human or bovine tuberculosis (as caused by their respective bacilli) is the same disease.
The second question propounded above is answered in the affirmative (although in no instance was the human type of tubercle bacillus isolated from cattle suffering from natural tuberculosis) as follows: "Mammals and man can be reciprocally infected with the disease (tuberculosis)." but whether reciprocity with the fowl and other birds exists must for the present remain unanswered. Mammals generally, with the exception of the rabbit and mouse, were not susceptible to infection with the avian type of bacillus. In addition to this it is pointed out that "bovine animals are not completely immune to the human tubercle bacillus, and adult human beings can be infected with the bovine type, even the pulmonary form of the disease in man being sometimes caused by the bovine tubercle bacillus."

In regard to question 3, the commission concludes "that the evidence accumulated goes to demonstrate that a considerable amount of the tuberculosis of childhood is to be ascribed to infection with bacilli of the bovine type transmitted to children in meals consisting largely of the milk of the cow."

For previous interim reports see earlier notes (E. S. R., 10, p. 181; 21, p. 481).

The tuberculo-opsonic index in man and bovine, STREIBELL and FELBER (Centbl. Bakt. [etc.], I. Abt., Orig., 54 (1910), No. 1, pp. 44-73; abs. in Internat. Centbl. Gesam. Tuberkulose Forsch., 4 (1910), No. 11, p. 566).—The results of 865 determinations with 50 tuberculous subjects show that 38 per cent gave a normal index (between 0.9 and 1.1), 33 per cent were below normal, and the remainder above normal. With healthy bovines the values in 98 per cent of the cases were normal with the human tubercle bacillus, and in 71 per cent of the cases with the bovine type, with 21 per cent of the bovine type above normal. With tuberculous bovines the values with the human type were normal for 83 per cent, and with the bovine type for 58 per cent, with 34 per cent of the bovine type above normal. The active sera of bovines artificially infected with the human tubercle bacillus had normal values in 51 per cent of the cases for the human type bacillus, and in 45 per cent for the bovine type bacillus. With the human type 46 per cent of the values were below normal, and for the bovine type 52 per cent.

About anaphylaxis in tuberculosis, C. VALLARDI (Ztschr. Immunitätsf. u. Expt. Ther., I. Orig., 7 (1910), No. 3, pp. 381-388).—Proceeding according to the methods utilized by other workers, typical anaphylactic symptoms could not be noted. Objective symptoms such as a fall in temperature and the lowering of complement were also absent.

Action of ovarian substance upon tubercle bacilli, H. WITTKENSTEIN (Wiener Klin. Wechschr., 22 (1909), No. 51, pp. 1785-1788, figs. 2; abs. in Centbl. Bakt. [etc.], I. Abt., Ref., 46 (1910), No. 13-14, pp. 398, 399).—Tubercle bacilli which were kept in ovarian extracts for from 15 to 20 days lost much of their virulence.

About tuberculosis immunity—Immunity in active tuberculosis, R. KRAUS and R. VOLK (Wiener Klin. Wechschr., 23 (1910), No. 19, pp. 699-701; abs. in Internat. Centbl. Gesam. Tuberkulose Forsch., 4 (1910), No. 11, p. 563).—The results show that resolved or healed tuberculosis leaves no immunity behind, and therefore indicate that no immunity can be expected by vaccinating with virulent bacilli. Furthermore, it is apparent that it is not possible to immunize
a normal subject against tuberculosis. Tubercular subjects are the only ones which can be immunized.

Immunizing against tuberculosis in guinea pigs, G. Deycke and H. Much (Beitr. Klin. Tuberkulose, 15 (1910), No. 2, pp. 277–302; abs. in Internat. Centbl. Gesamt. Tuberkulose Forsch., 3 (1910), No. 12, p. 628).—The author was able by means of dissolved tubercle bacilli and lecithin to immunize against a following infection with tubercle bacilli.

Control of bovine tuberculosis in British Columbia, M. A. Jull, A. Knight, and H. H. S. George (Brit. Columbia Dept. Agr., Live Stock Dept. Bul. 32, 1911, pp. 52, figs. 5).—The first part of this bulletin contains the report of the International Commission on the Control of Bovine Tuberculosis, which has been previously noted (E. S. R., 25, p. 384). Part 2 deals with bovine tuberculosis in British Columbia and its eradication, and is illustrated by photographs of diseased animals and pathological preparations made therefrom. The text of the contagious diseases (animals) act is also given.

Scabies (mange) in cattle, E. L. Moore (South Dakota Sta. Bul. 131, pp. 203–214, figs. 3).—A popular account describing the symptoms, diagnosis, and treatment.

A note on the occurrence of pentastomes in Australian cattle, T. H. Johnston and J. B. Cleland (Jour. and Proc. Roy. Soc. N. S. Wales, 44 (1910), pt. 3, pp. 315–318).—The authors record the occurrence of a larval pentastome (Pentastomum denticulatum), the adult of which is known as Linguatula serrata, in the mesenteric glands of Illawarra cattle suffering from endemic hematuria at Berry, New South Wales. This is said to be the first record of its occurrence in Australia.

Endemic hematuria ("Illawarra redwater") in cattle, due to angiomata in the bladder: Its possible relation to pentastomiasis, J. B. Cleland (Jour. Prop. Vet. Sci., 6 (1911), No. 2, pp. 125–133, pls. 2).—"Endemic hematuria (Illawarra redwater) is a distinct entity. It is common in the coastal districts of New South Wales. Evidently the same disease existed near Mt. Gambier in South Australia in 1894. Occasional cases occur in Victoria and probably it is the same disease that exists in Fiji and other Pacific Sea islands. It is characterized by hematuria of vesical origin, due to the bleeding from small angiomatous tumors in the bladder. The condition, as evidenced by the frequent presence of small papillomata and rarely, in long standing cases, by the appearance of carcinoma, is due to some form of chronic irritation. Larval pentastomes, living or calcified, have been found in considerable numbers in the mesenteric glands of all cases examined. They have also been found, but less frequently and usually in smaller numbers, in unaffected animals from the same and other districts. It is possible that the bladder lesions may be caused by the escape of these parasites through the bladder. This is the most probable etiological cause that has so far presented itself to careful investigation... The larval pentastomes have not so far been detected in the bladder."

An experiment in fumigation of ticks, C. W. Howard (Parasitology, 4 (1911), No. 2, pp. 164–167).—The experiments here reported were conducted in order to determine whether ships bringing cattle from Madagascar to Portuguese East Africa could be cleaned of the ticks which might have dropped from the cattle and thus be used in the transport of clean cattle for breeding purposes.

On March 6, 6 species of ticks in different stages, including eggs, unengorged larvae, unengorged nymphs, unengorged and engorged females, and males of
Margaropus decoloratus, eggs, unengorged nymphs, unengorged and engorged females, and males of Amblyomma hebraum, unengorged females and males of Rhipicephalus appendiculatus, and unengorged and engorged females and males of R. evertsi, R. simus, and Ornithodoros moubata were placed in a bale of hay, a box of sawdust, wrapped in 3 sheets of brown wrapping paper and placed inside a shoe box, and in a jar wrapped in cotton wool. All were then exposed for 12 hours to an atmosphere of 15 per cent Clayton gas (SO₂). On March 23, after several examinations, it was found that every tick had been killed.

This and other experiments led the author to conclude that "the Clayton gas (SO₂) is effective in killing ticks in the holds of cattle ships, when closed tightly, and is able to penetrate fairly dense substances. While, however, it is effective in destroying or preventing movement of live ticks, it is not absolutely effective in destroying entirely the vitality of engorged female ticks, so that an occasional one may survive to lay eggs, a portion of which may hatch. The system is therefore effective in cleaning ships from diseases which are transmitted from one stage of the ticks to the other, but where the disease can be transmitted through the eggs it is not entirely effective."

The manner in which the ox warble (Hypoderma bovis) enters the host, M. Strún (Hyg. Viande et Lait, 5 (1911), No. 7, pp. 393-397; Jour. Meat and Milk Hyg., 1 (1911), No. 7, pp. 397-400).—The author, who is veterinary inspector for the Board of Agriculture of Denmark, has reported in a previous article "that penetration of the larva takes place through the esophagus as well as through the skin, and also, in the majority of cases, that the larve which penetrate through the skin develop, whilst those which penetrate through the esophagus die."

In this article he records further observations (made in the lumbar region) of the entire length of canals containing the larve, which he thinks furnish proof that the canals start at the surface of the skin and that the penetration of the larve takes place thereby.

Worm nests in Australian cattle due to Filaria (Onchocerca) gibsoni, with notes on similar structures in camels, J. B. Cleland and T. H. Johnston (Jour. and Proc. Roy. Soc. N. S. Wales, 44 (1910), pts. 1, pp. 156-160; 2, pp. 161-171).—In this paper the authors deal with the historical and pathological sides of the subject. See also previous notes (E. S. R., 24, p. 785).

The nasal fly of sheep (Estrus ovis) in Australia, W. W. Froogatt (Agr. Gaz. N. S. Wales, 22 (1911), No. 3, pp. 223-227, pl. 1).—The author states that an increased number of complaints of parasitism of sheep by this fly are being received.

Hog-cholera serum, E. A. Burnett (Nebraska Sta. Rpt. 1910, pp. XVII, XVIII).—It is stated that 14,000 minimum doses of hog-cholera serum had been produced, prior to the date of writing, which had been used in part on 8,800 hogs, averaging in weight 130 lbs., with a loss of less than 7 per cent. These hogs represented 116 different outbreaks in 39 counties. It is estimated that for the $5,000 invested for serum, there will have been a direct saving of $75,000 in addition to the indirect saving in stopping outbreaks early and preventing further spread. It is further stated that, based on estimated prices, the cost of producing a dose of serum was about 5 per cent of the value of the hog.

The ascarid in the horse and its removal with tartar emetic, Grimmé (Deut. Tierärztl. Wehnschr., 19 (1911), No. 16, pp. 247-249; abs. in München. 17732°—No. 9—12—7
The most effective remedy for the removal of Ascaris megalocephala from the horse, according to the author, consists of giving from 15 to 20 gm. of tartar emetic in fractionated doses as follows: The tartar emetic is dissolved in a bucketful of water and one-third of it is given at 6 o'clock in the morning (water being withheld from the animals since the night previous), the second third at 8 o'clock, and the last at 8.30. After this treatment cathartics are usually unnecessary, but feeding beets or bran may aid the process considerably.

A contribution to the knowledge of the occurrence and development of Sclerostomum edentatum, O. Martin (Arch. Wiss. u. Prakt. Tierheilk., 37 (1910), No. 1–2, pp. 106–131, pl. 1, figs. 2).—Following a brief review of the literature, the author reports upon investigations of the biology of S. edentatum, its infestation of equines of different ages, etc.

Of 426 horses examined in the course of a year at the Hamburg abattoir 214 were found to be infested by this nematode. In these horses the worms were found in the subserosa of the parietal peritoneum in 139 cases and in the large intestine in 180. They were found both in the intestine and beneath the parietal peritoneum in 105, beneath the parietal peritoneum alone in 34, and in the intestine alone in 75 cases. Of 495 additional horses in which only the subserous tissue of the parietal peritoneum was examined 102 were infested.

A bibliography of 41 titles is included.

Notes on ovarian infection with Bacterium pullorum (Rettger) in the domestic fowl, G. E. Gage (Jour. Med. Research, 24 (1911), No. 3, pp. 491–496).—B. pullorum was isolated from the ovaries of 3 domestic fowls and in some instances in pure culture.

From one of the cases 12 ova were used for preparing agar and bouillon cultures, which were tested as regards virulence as follows: "Eighty-two chicks which had been incubated under proper conditions were used for this test. Sixty-two were inoculated, 30 by subcutaneous injections of a small amount of a bouillon culture of Bacterium pullorum, and 32 received 2 drops of a bouillon culture of the organism by the mouth. These inoculations were made at the end of 24 and 48 hours respectively. The remaining 20 healthy chicks were kept under the same conditions as the inoculated chicks. Every chick in the check lot was alive and healthy at the end of 6 weeks when this test was considered concluded." while 60 of the 62 infected birds died.

A post-mortem examination of each chick was made, and according to the author the results obtained corresponded well with Rettger and Stoneburn's pathological findings (E. S. R., 25, p. 590). He believes that there can be no doubt that B. pullorum is the causative agent for white diarrhea in chicks. The organism was reisolated in each instance.

About transferable fowl leukemia, H. Hirschfeld and M. Jacoby (Berlin. Klin. Wochenschr., 46 (1909), No. 4, pp. 159, 160; abs. in Zentral, Gesam. Physiol. u. Path. Stoffwechsels, n. ser., 5 (1910), No. 9, pp. 356, 357).—The results of tests with 2 diseased fowls which presented the typical leukemic symptoms are reported. The blood from these animals was transferred through 4 generations, and in each instance the blood of the inoculated animal showed the typical picture of leukemia and contained tubercle bacilli. It is concluded that even tubercle bacilli can bring about an enormous increase in certain leucocytes in the blood which reminds one of leukemia.

In regard to an epizootic of an unknown chicken disease, M. Eggberthe (Ztschr. Infektionskrank. u. Hyg. Haustiere, 5 (1909), No. 5, pp. 453–458; abs. in Berlin. Tierärztl. Wochenschr., 26 (1910), No. 5, p. 116).—Along with chicken cholera there occurs yearly in Tsinchuan, China, an acute febrile disease which causes a large mortality among chickens. It is caused by an ultravisible filter-
able virus which accumulates in the blood, organs, and in the secretions and excretions. Experimental tests showed the incubation period to be a very short one and that death occurred in 2 to 3 days. Geese, ducks, rabbits, and mice could not be infected, while pigeons could be infected occasionally. The author believes the disease to be pestis gallinarum (fowl plague).

The filaria (Oxyspirura mansonii) of the conjunctival sac of fowls, H. Fujita (Abs. in Rev. Gén. Méd. Vét., 17 (1911), No. 204, pp. 707, 708).—The author reports that the fowls of Formosa nearly always harbor this filaria in abundance in the conjunctival sac.

On Australian avian entozoas, T. H. Johnston (Journ. and Proc. Roy. Soc. N. S. Wales, 44 (1910), pt. 1, pp. 81–122).—The author has here brought together under each host a list of the endoparasites recorded as occurring in birds in Australia, as well as the references to their occurrence.

RURAL ENGINEERING.

Irrigation under the Carey Act, A. P. Stover (U. S. Dept. Agr., Office Expt. Sta. Rpt. 1910, pp. 361–388, pls. 2).—The text of the Carey Act and its subsequent amendments is given, together with a discussion of the causes which led up to the adoption of the act and the several amendments; an account of the operation of the law in the 8 States and Territories which have accepted its provisions; lists of irrigation companies operating under the Carey Act, showing acreage, estimated cost of systems, and maximum price of water per acre; and other data. A table summarizing the development accomplished under the provisions of the act follows:

Development accomplished in the West under the provisions of the Carey Act.

1 Exclusive of Ute Indian Reservation.

Irrigation and agricultural practice in Arizona, R. H. Forbes (Arizona Sta. Bul. 63, pp. 83, pls. 8, figs. 8).—This is a reprint of Bulletin 235 of this Office, previously noted (E. S. R., 25, p. 488). It also includes supplementary data showing the area irrigated in 1900 (306,665 acres), the assessed value of property in 1911, and the value of live stock on farms and ranges.

Development of methods of draining irrigated lands, C. G. Elliott (U. S. Dept. Agr., Office Expt. Sta. Rpt. 1910, pp. 489–501, pls. 4, figs. 2).—This article discusses causes which produce seepage in irrigated lands and methods of drainage applicable to the arid regions. Methods in use in the Bear River Valley, Utah, western Colorado, and elsewhere are described, together with data on the use of collecting pits and sand traps, special relief wells and discharge drains, steam land dredges, cement drain tile and wooden box drains, the pumping of drainage waters from sumps into irrigation ditches, and cooperative drainage projects.
It is pointed out that drainage practice in irrigated regions differs materially from ordinary practice in the humid sections. Under the usual conditions in irrigated fields 6 ft. is found to be about the minimum depth advisable. The frequent use of a few well located and deep drains to intercept the underflow before it reaches the land which requires drainage is another striking difference. The method of draining by relief wells, an adaptation of the Elkington system of tapping underground springs, is emphasized as especially applicable to the improvement of saturated irrigated lands.

It is estimated that there are at least 800,000 acres of irrigated land which now require drainage to make them profitably productive.

**Tidal marshes and their reclamation, G. M. Warren (U. S. Dept. Agr., Office Expt. Sta. Bul. 249, pp. 99, pls. 16, figs. 21).—**This bulletin reports special investigations of two reclamations in New Castle County, Del., and two in Cumberland County, N. J. These reclamations have been carefully surveyed, current-meter measurements made of the sluice discharges, and the results studied in considerable detail from agricultural, engineering, and economic standpoints. The forepart of the report contains a definition of terms and a short discussion of tides. Following detailed descriptions of the experimental marshes a general summary and discussion covers the proper character, construction, and maintenance of sluices, levees, ditches, and pumping plants, soils, ground-water vegetation and its relation to the water-table, treatment of lands and crops grown, and financial and sanitary aspects. There are also brought out the reasons for poor progress and causes of failure in so many of the tidal reclamations of the past, and the questions which should be decided before any reclamation is undertaken are discussed.

Supplemental investigations are reported of the marsh lands at Green Harbor, Mass., and others in New England, New Brunswick, and Nova Scotia. A rather complete history of the first-mentioned reclamation is given in order to bring out the legal aspects of the questions often involved in attempted reclamations.

In conclusion, the author explains the success of tidal reclamations on the Bay of Fundy, and the apparent indifferent success which has attended many of the reclamations farther south along the Atlantic Coast, as follows: "Unquestionably the fundamental reason lies in the great nature-bestowed gift of a large range of tide, which has built the marshes high and permits the sluices to play long periods of time, thus securing adequate drainage easily, cheaply, and certainly. There are, of course, other reasons of historical, physical, and economic nature which have contributed, but they are relatively insignificant and are more than offset by our own economic needs and by American energy, enterprise, and resourcefulness."

**Dynamite for preparing land, J. T. Garrett (New England Homestead, 63 (1911), No. 15, p. 318).—**In giving his experience with the use of dynamite for subsoiling for corn, the author states that rows were marked 15 ft. wide and plowed out with a 1-horse turning plow. With a 1½ in. steel bar holes were made in this furrow 40 in. apart and 30 in. deep into the subsoil and through hardpan, loaded with one-half of a ½ lb. stick of dynamite, and several holes fired at one time. A yield of 120 bu. of corn per acre was obtained. An adjoining area of the same size subsoiled with a plow and mules produced 82 bu. per acre.

The author also states his experience with dynamite in growing melons. He expects beneficial results from this dynamiting for at least 10 years.

**Examination and classification of rocks for road building, including the physical properties of rocks with reference to their mineral composition and structure, E. C. E. Lord (U. S. Dept. Agr., Office Pub. Roads Bul. 37, pp. 28. pl. 10, fig. 1).—**This is a revision of Bulletin 31 of the Office of Public
Roads (E. S. R., 19, p. 385), which it supersedes, and describes methods of petrographic examination and classification of rocks used in road making with other “facts of importance bearing on the relation of the physical properties of rocks to their mineral composition and structure.”

Highway bridges and culverts, C. H. Hoyt and W. H. Burr (U. S. Dept. Agr., Office Pub. Roads Bul. 39, pp. 22, pls. 14, figs. 3).—This bulletin presents a general discussion of the status of highway bridge and culvert construction, summarizing data as to previous methods, and making suggestions as to methods now in vogue and the assistance being rendered in such construction by the Office of Public Roads of this Department.

“The relation of culverts and bridges to the general movement for the improvement of our public highways is intimate. The desirability and economy of building these structures of durable and permanent material, or according to intelligent or economic design, has not thus far been actually recognized in practice throughout the United States. The expensive and unsatisfactory method of repairing the old and inadequate structures of the past or of fording the streams is still continued. Modern traffic now demands that the construction of bridges and culverts shall keep pace with industrial development.”

Descriptive catalogue of the road model exhibit (U. S. Dept. Agr., Office Pub. Roads Bul. 36, pp. 29, pls. 14, fig. 1).—This bulletin embodies data originally compiled for use in explaining the exhibit of the Office of Public Roads at the Alaska-Yukon-Pacific Exposition. It describes in detail the models used to illustrate the construction of road foundations, earth, sand, clay, gravel, macadam, and brick roads, and presents data as to road machinery.

The use of concrete on the farm (U. S. Dept. Agr., Farmers' Bul. 461, pp. 23, figs. 10).—In this publication, which supersedes Farmers' Bulletin 235, previously noted (E. S. R., 17, p. 769), suggestions for mixing and handling concrete under farm conditions are presented. Data are given on the selection of materials and the manufacture of concrete, the use of measuring boxes and other equipment for mixing concrete, and the construction and use of forms.

Silo construction, A. S. Kenyon (Jour. Dept. Agr. Victoria, 9 (1911), Nos. 7, pp. 492-503; 8, pp. 566-573, figs. 9).—Details are given for building steel, cement, wood, and wood and iron silos.

Reinforced brick silos, R. T. Archer (Jour. Dept. Agr. Victoria, 9 (1911), No. 8, pp. 571-576, figs. 2).—Details are given for the construction of an economical type of brick silo, reinforced with galvanized wire.

The plastered or Gurler silo, H. E. McNatt (Missouri Sta. Circ. 48, pp. 167-114, figs. 9).—Directions are given for building the plastered or Gurler silo.

The reinforced concrete silo, F. H. Demaree (Missouri Sta. Circ. 49, pp. 115-122, figs. 4).—Directions are given for constructing a reinforced concrete silo. A reinforced stone silo in use on the college farm at Columbia, Mo., is illustrated and briefly described.

Poultry house construction, D. O. Baro (Farmers Voice, 49 (1911), No. 114, pp. 3, 13, fig. 1).—A discussion of poultry house construction. An open-front, “half-monitor” type of poultry house constructed of hollow cement blocks, recently built at the Illinois Station, is illustrated and described.

[Design for farm buildings on small holdings] (Country Life [London], 30 (1911), No. 756, pp. 11*, 12*, fig. 9).—This plan for a cottage, barn, and outbuildings for an English holding of about 50 acres received the first prize in the competition of the recent show of the Royal Agricultural Society of England.

The sanitary privy, C W. Stiles and L. L. Lumsden (U. S. Dept. Agr., Farmers' Bul. 463, pp. 32, figs. 9).—Soil pollution and the diseases spread from man to man in this way are discussed, the various kinds of privies described,
and detailed directions presented for building a sanitary privy and keeping it in proper condition.

The L. R. S. privy, an apparatus devised by Lumsden, Roberts, and Stiles consists of the following parts: "(1) A water-tight barrel or other container to receive and liquefy the excreta.

"(2) A covered water-tight barrel, can, or other vessel to receive the effluent or outflow.

"(3) A connecting pipe about 2½ in. in diameter, about 12 in. long, and provided with an open T at one end, both openings of the T being covered with wire screens.

"(4) A tight box, preferably zinc lined, which fits tightly on the top of the liquefying barrel. It is provided with an opening on top for the seat, which has an automatically closing lid.

"(5) An antisplashing device consisting of a small board placed horizontally under the seat about an inch below the level of the transverse connecting pipe; it is held in place by a rod, which passes through eyes or rings fastened to the box, and by which the board is raised and lowered. The liquefying tank is filled with water up to the point where it begins to trickle into the effluent tank.

"As an insect repellent a thin film of some form of petroleum may be poured on the surface of the liquid in each barrel."

This device is believed to eliminate the fly and mosquito problem, liquefies fecal material, reduces odor and the labor of cleaning, and is of simple and inexpensive construction.

Water power for the farm and country home, D. R. Cooper (New York: State Water Supply Com., 1911, pp. 45, figs. 30).—The installation of power-driven machinery and its advantages are discussed, as well as the development of electric power from water power and related questions.

RURAL ECONOMICS.

It is shown that the increase in the number of farms has not kept pace with the increase in population, the number of farms having increased 10.5 per cent, while the total population shows an increase of 21 per cent. A decrease is reported in the average size of farms from 146 acres in 1900 to 138 acres in 1910, but the improved land has increased from 414,499,000 acres in 1900 to 477,448,000 acres in 1910, a gain of 15.2 per cent. The average value of farm property is shown to have increased from $15.57 per acre in 1900 to $32.49 per acre in 1910, an increase of 108.7 per cent.

The factors mentioned as contributing to the increased value of farm land include the advanced farm prices of agricultural products; capitalizing the income-producing power at a lower rate of interest than formerly; the cost of improving what was previously unimproved land; the depletion of desirable free land resulting in an increase in the number of buyers; an increased demand for homes in the open country; and the expenditure of much labor and money on various kinds of improvements, such as the building of roads, bridges, schoolhouses, and other rural improvements.

The following table shows more detailed data as to general agricultural operations:

  - **-66,198** | **73,432,535** | **1.7** | **57.3**
It is pointed out that the aggregate value of all live stock, including the common domestic animals, poultry, and bees, has increased 59.2 per cent since 1900. The value of cattle, however, has increased only 0.7 per cent, while the increase in the value of horses has been 131.6 per cent.

The total number of farms reporting poultry increased 9.6 per cent during the decade. The total number of fowls increased 18.1 per cent, and the increase in their value was 78.9 per cent, the total number of fowls being 2,955,876,176, and the total value $153,394,000 in 1910. Other tables are given showing the value of live stock by classes and geographic divisions in 1910 and 1900, and by farms reporting, and the number, value, and average value of domestic animals by age and sex groups in 1910.

Land values and land prices in the East and in the West, G. F. Warren (N. Y. Dept. Agr., Rpt. Farmers’ Insts., 1908-9, pp. 69-83, pls. 3).—In this address the author points out the extreme importance of capital as a factor in determining the profits that the farmer is able to make, and expresses the opinion from a statistical study that the failure of many a good farmer is primarily due to a lack of capital to manage his business properly. He calls attention to the depreciation of land values and prices in the East as compared with those of the West, showing that land values in New York State depreciated 11 per cent from 1890 to 1900. This he attributes to the development of free land in the West, together with the prevalence of farms of too small area in the East and their nearness to cities which easily attracted boys away from them upon the slightest depreciation of business.

Tables are given contrasting the average yields and values per acre of the 5 leading crops in representative States of the 2 sections for a period of 10 years, showing that during that period the average values per acre of these 5 crops have been $19.42 in New York, $16.70 in Illinois, and $13.96 in Iowa. Other data are given contrasting the price of farm lands, the cost of pasture land, and farm crops statistics, together with their values, etc.

Farms for sale or for lease in Rhode Island (R. I. Conserv. Com. Bul. 1, 1911, pp. 278, pls. 17, map 1).—This bulletin, issued by the Rhode Island State Conservation Commission, presents a detailed list of farms in Rhode Island for sale or for lease, with special reference to the needs of prospective purchasers.

Survey of Alaska lands, M. D. Snodgrass (Alaska Stas. Rpt. 1910, pp. 65-69).—This report shows the results of a brief and cursory survey of the available agricultural land in the Tanana Valley. A greater portion of the report is based on interviews with prospectors and hunters met by the author at different landings along the river, though personal observations were made wherever practicable.

The Valley is reported to be 300 miles long and from 30 to 70 miles wide, aggregating, together with the valleys of various tributaries, about 15,000 square miles of valley land. The southern slopes of the hills in various parts of the Valley are thought to be good farming lands. The lowlands, where drainage is possible, would often produce abundantly but crops here are in greater danger of midsummer frosts.

Letters from settlers (Alaska Stas. Rpt. 1910, pp. 69-76).—Communications from settlers in various parts of Alaska concerning their success in gardening, cattle raising, or other agricultural enterprises, are given, especially their results with the seed distribution.

A practical farmer engaged in stock raising and general farming for several years in the coast region of southeastern Alaska calls attention to the difficulty of securing profitable farm help because of the high prices paid for labor in
other industries. Large scale farming is also handicapped in that section of Alaska, because of the small areas of arable land, the expense of clearing land, and the prevalence of chickweed. Grasses are thought to offer the greatest agricultural possibilities and stock raising is considered the most promising line of farming.

Agriculture (Stat. Jahrb. Schwiz, 19 (1910), pp. 40-64).—Tables taken from results of the industrial census in Switzerland August, 1905, are given, showing (1) the total number of persons engaged in agriculture according to sex, class, size of farm, age, and nationality, (2) the legal relation as to ownership of farms, (3) the kind of farming as indicated by the size and extent of farms, and the number of persons engaged, (4) itinerant farm laborers, (5) the acreage devoted to different farm purposes, and (6) the utilization of machinery and other tools on farms.

Out of 763,915, the total number engaged in agriculture, 56.6 per cent were males; 14.6 per cent were over 14 and under 20 years of age; 71.7 per cent over 20 and under 60 years of age, and 13.7 per cent 60 years and over; 97.2 per cent were Swiss, and the remainder Germans, Austro-Hungarians, Italians, and French.

[Agricultural machinery, live stock, etc.] (Stat. Jahrb. Deut. Reich, 32 (1911), pp. 31-42).—Tables and statistics collected by the German Government showing the use of farm machinery in different kinds of agricultural work, an inventory of live stock, and data as to agricultural enterprises conducted on farms of varying sizes in the several states of Germany, are presented.

The following table shows the kind and number of implements used in the Empire on 5 sizes of farms:

Agriculture (Diplo. and Cons. Rpts. [London], Ann. Ser., 1911, No. 4781, pp. 57-59).—With respect to agriculture this report points out that the future outlook of the Russian peasant is to an extent encouraging, as the government and public institutions are now giving him effective help in several ways. “By being freed from the village community he gains the incentive of private ownership of his land; the Peasants’ Agrarian Bank helps him to purchase land to be worked as independent small farmsteads; the cooperative and credit associations give him the credit necessary to purchase seed, cattle, and implements.”

The Zemstvos are reported as aiding the peasants materially through their test farms where the peasants see the concrete results of better farming. Through lectures and demonstrations they also teach the peasants how to increase the yield of their farms and show them the advantage of longer rotations of crops, the use of better types of farm implements, and the proper cultural methods.
Annual report of the Agricultural Organization Society, Limited, for
1910, pp. 158, figs. 26).—This report shows the progress of the Central Coopera-
tive Bank, founded in 1908 for the purpose of making advances at moderate
rates of interest to cooperative societies in England and Wales. The advances
made in 1910 nearly doubled those of 1909, and in many instances provided
funds which were not obtainable from any other source.

The report shows that steady progress is being made in the direction of co-
operative insurance. The society, founded with funds of £20,000, now has avail-
able funds exceeding £27,000 to meet all claims, while bonuses at the rate of
25 per cent have been declared for the years 1909 and 1910.

The progress of the affiliated societies is also summarized.

Statis. Circ. 24, pp. 15).—This circular summarizes data as to the condition of
farm crops in foreign countries in September, 1911, with estimates of yields
as compared with previous years.

AGRICULTURAL EDUCATION.

Progress in agricultural education, 1910, D. J. Crosby (U. S. Dept. Agr.,
Office Expt. Stats. Rpt. 1910, pp. 315–386, pls. 9, figs. 3).—This is a review for
1910 of the leading features of progress in agricultural education in this country
and abroad, including the educational work of this Department, the Association
of American Agricultural Colleges and Experiment Stations, the National Educa-
tion Association, the fourth session of the Graduate School of Agriculture, the
principal developments in agricultural education in foreign countries, and the
leading items of interest concerning the colleges of agriculture in the United
States, normal schools, and secondary and elementary schools in which agricul-
ture is taught. The data concerning the elementary schools contain plans
for a model rural school.

Statistics of land-grant colleges and agricultural experiment stations,
271–314).—A compilation from official sources of general statistics, courses of
study, attendance, value of funds and equipment, revenues, and additions to
equipment of the land-grant colleges, and of the lines of work, revenues, and
additions to equipment of the agricultural experiment stations in the United
States for the fiscal year ended June 30, 1910.

Correlating the work of agricultural instruction, A. C. True (South Ed.
Assoc. Jour. of Proc., 21 (1910), pp. 76–82).—It is stated in this paper that
"the settlement of the general limitations of the work of different grades of
schools will do much to clarify and improve our educational situation. This
is the task before our generation." The function as regards teaching agriculture
is discussed for elementary schools, high schools, the agricultural high school,
normal schools, and colleges and universities. The problem of so managing the
school farm that it will be the right kind of laboratory and demonstration farm
for a secondary school is deemed as yet an unsolved problem of very
great importance, and an earnest effort to solve this problem is considered more
to be commended than an attempt by the secondary school teacher to engage in
ordinary extension work or in so-called experiments.

Preparing teachers to give instruction in agriculture, J. F. Duggar (South
Ed. Assoc. Jour. of Proc., 21 (1910), pp. 142–146).—The agencies at work in
training teachers to give instruction in agriculture are enumerated, and it is
stated that in fitting the teacher there must be imparted 3 distinct elements
of success: (1) inspiration and a reasonable confidence in the importance of the end to be attained; (2) abundant subject-matter; and (3) some slight instruction regarding methods of teaching agriculture.

The author's recommendations as to the lines in which progress can best be made are as follows: "(1) More universal inclusion in the curriculum of normal schools of agricultural instruction, given by a specialist; (2) daily instruction and demonstrations in agriculture in teachers' institutes; (3) extension work in agriculture by universities and colleges for the special benefit of teachers; and (4) the gradual introduction, first by the more progressive and wealthier counties, of the system of employing supervisors of agricultural instruction."

The high school course in agriculture, K. L. Hatch (Bul. Univ. Wis., 1911, No. 441, pp. 40).—With the expectation that instruction in agriculture will find its way into the high schools of Wisconsin this bulletin has been prepared to suggest suitable plans for the carrying out of this work. It contains among other things (1) a suggested arrangement of work in agriculture and related sciences for each of the 4 years, (2) details of each unit of work, (3) a syllabus of a 4-year secondary course in agriculture as prepared by this Office, (4) necessary laboratory supplies for a class of 12 with estimated price, (5) text and reference books, including publishers' and list price, (6) a selected list of bulletins of this Department recommended for school use, and (7) a bibliography on agricultural education prepared by the U. S. Bureau of Education.

The farmers' institutes in the United States, 1910, J. Hamilton (U. S. Dept. Agr., Office Expt. Stas. Rpt. 1910, pp. 387–424).—This is the annual report of the Farmers' Institute Specialist of this Office for 1910 concerning the work of the Office in promoting farmers' institutes and the development of the farmers' institute movement in the different States and Territories. It includes, among other things, a discussion of agricultural college and experiment station aid to institutes, extension agencies, an account of the institutes for women and young people, county fair associations, the principal points of progress by States and Territories, an account of the annual meeting of the American Association of Farmers' Institute Workers, and statistical tables showing the number of institutes held, attendance, funds appropriated, cost, and number of lecturers employed.

Legislation relating to farmers' institutes in the United States, J. Hamilton (U. S. Dept. Agr., Office Expt. Stas. Bul. 241, pp. 47).—This is a revision of Bulletin 135 of this Office (E. S. R., 17, p. 715), bringing information concerning legislation on farmers' institutes up to April 1, 1911.

What Purdue is doing for Indiana agriculture (Indiana Stn. Circ. 28, pp. 52, figs. 45).—Information is here furnished concerning the work of the several departments of the agricultural experiment station and the school of agriculture, and of the department of agricultural extension.

The results of agricultural extension in Belgium, J. M. Stedman (U. S. Dept. Agr., Office Expt. Stas. Rpt. 1910, pp. 425–447).—This is a translation and summary of a monograph on agriculture in Belgium from 1885 to 1910, prepared by the minister of agriculture of that country for the twenty-fifth anniversary of the establishment of the Office of Extension Supervisors. The report contains a statistical statement concerning the rise in price of agricultural lands in Belgium and the increase in their productive power during the last 25 years, and an account of the organization and work of the extension supervisors and of the development of agriculture in each Province and the part taken therein by the extension supervisors from 1885 to 1910.
Live stock judging for beginners (Indiana Sta. Circ. 29, pp. 128, figs. 99).—This circular, prepared under the direction of J. H. Skinner, is designed primarily for beginners in the study of live stock judging.

It is divided into 6 parts and an appendix. Part 1, the introduction, considers the profitableness of the study of live stock judging, the score card, and comparative judging. Part 2. Judging Horses, by D. O. Thompson, includes draft, harness, and saddle horses, ponies, breeding classes, and the location of common unsoundness and faults. Part 3. Judging Beef Cattle, by F. G. King, treats of fat steers, feeder or stocker cattle, and breeding classes. Part 4, Judging Dairy Cattle, by P. H. Crane, considers the dairy cow and the dairy bull. Part 5. Judging Hogs, by W. W. Smith, treats of fat hogs, the brood sow, and the boar. Part 6. Judging Sheep, by H. E. Allen, is a study of fat and feeder sheep, breeding classes, and Merino or fine-wool type of sheep.

Score cards are given for draft horses, beef cattle, dairy cattle, lard hogs, and mutton sheep, as well as diagrams showing the points of the horse, beef animal, dairy cow, hog, and sheep, the wholesale cuts on the beef carcass and on the live steer, the wholesale pork cuts, and the mutton and lamb cuts. The appendix outlines a method of live stock improvement, by W. W. Smith, and contains a tabulation of breeds of live stock and breed associations, and lists of books and other publications about live stock.

Fruit for exhibition, A. J. Norman (Facts for Farmers [Mass. Agr. Col.], 1 (1911), No. 12, pp. 4).—Methods for preparing fruit for exhibition and suggestions for judging it are given, together with score cards for apples, plums, peaches, and grapes. The pamphlet is suitable for study in public schools.

Some health problems, E. L. Holton, F. H. Slack, and L. D. Buskeneli (Agr. Ed. [Kans. Agr. Col.], Rural Life Sern., 3 (1910), No. 1, pp. 15, figs. 13).—This article was prepared for the village and rural teachers of Kansas, and deals especially with stamping out typhoid fever by attention to the typhoid or house fly, the water supply, and the milk supply.

Nature study by grades, H. H. Cummings (New York, Cincinnati, and Chicago [1910], pp. 11+274, figs. 87).—This book is designed to meet the needs of pupils in the sixth, seventh, and eighth grades of elementary schools. The lessons are grouped into fall, winter, and spring work, and consist of suggestions to the teacher, questions, problems, and simple experiments in nature study.

Suggestions for girls' contests in sewing and cooking (Agr. Ed. [Kansas Agr. Col.], 2 (1910), No. 7, pp. 30).—This pamphlet was prepared with a view to bringing about more uniform work in institutes. The suggestions cover such matters as mending, sewing, score cards for bread, butter, and jellies, canning fruit and vegetables, and making butter under farm conditions.

MISCELLANEOUS.

Annual Report of the Office of Experiment Stations, 1910 (U. S. Dept. Agr. Office Expt. Stat. Rpt. 1910, pp. 512, pls. 29, figs. 8).—This includes the usual report on the work and expenditures of this Office for the fiscal year ended June 30, 1910, and of the work and expenditures of the agricultural experiment stations in the United States, including Alaska, Hawaii, Porto Rico, and Guam; statistics of the agricultural colleges and experiment stations for 1910, noted on page 896; and numerous articles and reviews abstracted elsewhere in this issue.

the fiscal year ended June 30, 1910. Meteorological data and accounts of the extensive tests with field and garden crops and of the live stock operations are abstracted elsewhere in this issue.

Seventeenth Annual Report of Montana Station, 1910 (Montana Sta. Rpt. 1910, pp. 235-261, figs. 2).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1910, a report of the director on the work and publications of the station, and a meteorological summary of temperature, precipitation, wind direction, sunshine, and frost conditions at Bozeman, Mont., during the year.

Twenty-fourth Annual Report of Nebraska Station, 1910 (Nebraska Sta. Rpt. 1910, pp. XXXIX+208, figs. 51).—This contains the organization list, a review of the work of the year, including notes on field crops and hog-cholera serum abstracted respectively on pages 830 and 837 of this issue, a financial statement for the federal funds for the fiscal year ended June 30, 1910, and for the remaining funds for the fiscal year ended July 31, 1910, and special articles abstracted elsewhere in this issue.

Annual Report of Nevada Station, 1910 (Nevada Sta. Bul. 1910, pp. 58).—This contains the organization list and reports of the board of control, the director, and heads of departments. The report of the director includes the financial statement for the fiscal year ended June 30, 1910. The experimental work reported in the departmental reports is abstracted elsewhere in this issue.

Thirty-third Annual Report of North Carolina Station, 1910 (North Carolina Sta. Rpt. 1910, pp. 206, figs. 102).—This contains the organization list, reports of the director and heads of departments, the experimental work in which is for the most part abstracted elsewhere in this issue, a financial statement for the fiscal year ended June 30, 1910, numerous special articles abstracted elsewhere in this issue, an account of some breeding experiments in progress, and reprints of Press Bulletin 21, Treatment of Oats, Wheat, Rye, and Barley for Smut, and of Bulletins 205-208, previously noted.

Annual Report of Pennsylvania Station, 1910 (Pennsylvania Sta. Rpt. 1910, pp. 632, pls. 70, charts 2).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1910, a report of the director on the work and publications of the station during the year, and departmental reports, the experimental work in which is abstracted elsewhere in this issue. The report also contains several special articles abstracted elsewhere in this issue, reprints of Bulletins 94, 96, 97, 99, and 100, previously noted, and a reprint, with some changes, of Bulletin 102.

Annual Reports of Virginia Station, 1909 and 1910 (Virginia Sta. Rpts. 1909-10, pp. 232, pl. 1, figs. 188).—This contains the organization list, a report of the director discussing the organization, finances, work, publications, and other data pertaining to the station, a financial statement for the fiscal years ended June 30, 1909, and June 30, 1910, departmental reports, of which that upon tobacco insect investigations is abstracted on page 854 of this issue, and numerous special articles abstracted elsewhere in this issue.

Free literature on farming, J. C. Marquis (Wis. Library Bul., 7 (1911), No. 1, pp. 16-19).—This article explains how free publications pertaining to agriculture may be collected and classified for use in libraries, with a view to making them more widely available.
California University and Station.—J. H. Norton, assistant chemist at the citrus substation at Riverside, has resigned to take effect February 1, 1912, when he will engage in commercial work.

Connecticut College.—An international egg-laying contest is being held at the college beginning November 1. Twelve States, Canada, and England are represented by 23 breeds. Fifty colony houses have been erected for the work.

Georgia Station.—L. J. Herring, assistant animal pathologist and veterinarian, has accepted an opening in commercial work.

Hawaiian Sugar Planters' Station.—Frank W. Terry, assistant entomologist, died November 7.

Louisiana University and Stations.—V. L. Roy, professor of agricultural extension work, has been appointed president of the State Normal School at Natchitoches. He is succeeded by E. S. Richardson, who will be assisted by W. H. Balis and Miss Agnes Morris.

A seed testing laboratory has been established at the Baton Rouge Station by the Bureau of Plant Industry of this Department. J. M. Moss is to be in charge of the laboratory.

E. S. Tucker, of the Bureau of Entomology of this Department, is to carry on investigations of insects affecting stored rice, and will make his headquarters at Baton Rouge after January 1, 1912.

Massachusetts Station.—J. F. Merrill has resigned as assistant chemist, this taking effect December 1.

Nebraska Station.—Miss Venus W. Pool resigned November 1 as assistant in agricultural botany to accept a position in the seed laboratory of the Bureau of Plant Industry of this Department.

Cornell University and Station.—Recent appointments include John Bentley, jr., of the Forest Service of this Department, as assistant professor of forestry, A. C. King, an 1899 graduate of the college of agriculture, as extension instructor, and Royal Gilkey, a 1908 graduate, as instructor in extension teaching.

Ohio Station.—D. W. Galehouse has been appointed assistant in charge of fair exhibits.

Oklahoma Station.—E. W. Stafford, whose resignation from the New Jersey Stations has been previously noted, has been appointed assistant entomologist.

Porto Rico Federal Station.—The position of entomologist has been filled by the appointment of Dr. Charles W. Hooker, of the Bureau of Entomology of this Department, who has entered upon his duties.

West Virginia University.—The inauguration of Dr. Thomas E. Hodges as president took place November 3. Among those in attendance during the exercises of the week were President Taft, who delivered an address on Judicial Settlement of International Disputes; Dr. F. B. Dresslar, of the United States Bureau of Education, who spoke on Duties and Opportunities of the Modern Scholar; President E. A. Alderman, of the University of Virginia, whose subject was The Universities and the National Spirit; President H. P. Judson, of the University of Chicago, who discussed The University and the State; and President W. O. Thompson, of Ohio State University, whose subject was The University and the People.

Lupus in man, relation to bovine tuberculosis... 783
Luzula spp., analyses, Wyo... 131
Lychnis dioica, reversible sex mutants in... 129
Lycopersicon arvensis, studies, U.S.D.A... 651
Lyctidae, studies and bibliography, U.S.D.A... 261
Lytocorys spp., list, U.S.D.A... 261
Lycus politus n. sp., description, U.S.D.A... 261
spp., list, U.S.D.A... 261
Lygusmonotum erichsorni in Minnesota... 58
Lygodia mendax, studies, N. Y. Cornell... 255
Lymphanodontis in sheep... 378
Lynx, new eustode parasite of... 757
Lypersia longipalpis, studies... 56
Iysiphilus flavidus n. sp., description, Md... 557
spp., notes, Md... 557
Macaroni, misbranding, U.S.D.A... 64, 468
wheat. (See Wheat, durum.)
Machinery. (See Agricultural machinery.)
Macroactylus subspinosus. (See Rose chafers.)
Macrophoma dyctiae n. sp., description... 47
Macrosiphum sanborni, notes... 461
Mammary glands—review of literature... 680
secretion, artificial stimulation... 167
Mammitis, acute contagious, in cows, cause... 88
diagnosis... 785
in cows, notes... 378
Man and animals, treatise... 470, 489
as affected by breathing oxygen-rich gas... 471
hog cholera affecting... 681
insects affecting... 250, 757, 832
maintenance requirements... 389
Malta fever affecting... 792
metabolism experiments... 570
in... 169, 309
rat fleas affecting... 762
respiration experiments... 270, 672
respiratory exchange in... 570
strength and endurance tests... 471
stronglygloes infections in... 783
Mandrake, variations in, N.J... 445
Manganese—
and zinc, effect on Aspergillus niger... 325
determination in soils... 512
effect on development of Aspergillus niger... 127
growth of pineapples, Hawaii... 340
plant growth... 520
yields... 522
soils... 122
function as a fertilizer... 827
metabolism of... 572
minimum in animals... 572
ocurrence in Italian soils... 512
role in plant nutrition... 731
salts, fertilizing value... 122
toxic effect on pineapples... 731
Mange. (See Cattle, Dog, Horse, and Sheep mange or seb.)
Mange, Babillus melangenes affecting... 454
breeding experiments... 35
culture experiments... 35, 230
dry-matter content... 906
feeding value... 70
fertilizer experiments... 217, 442
rotting disease affecting... 45
varieties... 333
Can... 329
Mango, weedwils, studies, U.S.D.A... 561
Mangos, culture in Florida... 540
host of cacao thrips... 832
insects affecting, Hawaii... 338
new, descriptions, U.S.D.A... 540
picking and packing experiments... 436
P.R... 741
preparation and use... 164
propagation, Hawaii... 337
varieties, P.R... 740
Mangold storage rot, studies... 245
Mangosteen notes, Hawaii... 337
Manna, Sicilian, analyses... 368
Mannite, effect on A. tabotabata chroococcus... 723
Mantids, Chinese, notes, N.J... 459
Manure, barnyard. (See Barnyard manure.)
chemistry of... 422
deterioration, Colo... 516
effect on activity of bacteria... 525
plant growth, Va... 825
effects of continuous use, Pa... 821
Meadows, fertilizer requirements .......... 32
liming experiments .......... 33
(See also Grasses.)

Meals, planning .......... 166
Mealy bug, remedies, Hawaii .......... 338
Measures and weights, law, Nev .......... 497
Meat, addition to vegetarian diet .......... 266
adulteration, detection .......... 189
effect on digestive leukocytosis .......... 571
examination .......... 165
extract, effect on resorption of nutritive
matter .......... 466
fertilizing value .......... 729
handbooks .......... 466
horse. (See Horse meat.)
industry, treatise .......... 263
ingestion, effect on dogs .......... 864
inspection—
bacteriological, necessity of .......... 268
in France .......... 282
Germany .......... 84
mouse-feeding test for .......... 84
statistics, U.S.D.A .......... 372
treatise .......... 268, 881
value of Xiphioid lymph-gland in .......... 84
market classes and grades, U.S.D.A .......... 85
meal, analyses .......... 272, 572, 570, 871
N. J .......... 774
pigs .......... 475
methods of analysis .......... 411
micro-organisms in .......... 265, 368
poisoning bacteria as affected by salt .......... 163
due to Proteus vulgaris .......... 452
preserving, Russian process .......... 163
price of in Germany .......... 774
products, albuminoses in .......... 566
industry in France .......... 71
refrigeration experiments .......... 65
in transit .......... 61
scrap, analyses, Mass .......... 71, 574
Me .......... 370
substitutes for, U.S.D.A .......... 567

Mechanical colleges. (See Agricultural
colleges.)

Medicago hispida, host plant of alfalfa cater-
pillar, U.S.D.A .......... 54
sativa, analyses, Wyo .......... 131
app, analyses .......... 32
description and culture .......... 132
notes, Nev .......... 831
Medlar, post-ripening of .......... 202
Megacyclus major, destructive to ticks .......... 60
Megarhinus spp., feeding habits .......... 359
Melampsoropsis spp., culture experiments .......... 43
Melenconia modonia, parasitic on chestnuts .......... 149
perniciosus (modonia), identity .......... 149
relation to chestnut
black canker .......... 880
Melanopus spp., notes, N.Dak .......... 657
Meliana albilinea, studies, Iowa .......... 55, 557
Melica spectabilis, analyses, Wyo .......... 131
Melilotus albus, host plant of alfalfa caterpillar, U.S.D.A .......... 54
sp, analyses .......... 32
description and culture .......... 32
Mellon aphis, remedies, Nebr .......... 882
canker, notes .......... 250

*Muscar* spp., descriptions ........................................... 546
Mucorinae, new organ of .............................................. 750
Mucus, affinity for hydrochloric acid ................................ 66
Mud, alluvial, arrest and utilization ................................ 626
Mulberry borer, notes .................................................. 251
Musis, parasitism ....................................................... 653
Mules, feeding experiments, N.C ...................................... 775
*Multiceps multiceps*, parasite in coyotes ......................... 882
*Multiceps serialis*, parasite in squirrels .......................... 883
Munroa squarrosa, analyses, Wyo ..................................... 131
*Murganti a histriocora*. (See Harlequin cabbage-bug.) ....... 442
Muriate of potash, fertilizing value, Ind .................................. 832
*Musa caviruina*, studies ............................................... 56
*Musa domestica*. (See House flies.) ................................ 260
Muscid larve, rearing .................................................. 671
Muscle proteins, effect on chemical reagents ....................... 370
Muscles, effect of training ............................................. 671
*Musculus* n., nitrogenous constituents of ......................... 67
Muscular work—
  effect on body expenditure ........................................ 671
  temperature ................................................................ 571
  storage of glycogen .................................................... 267
  energy problems in .................................................... 672
  relation to protein metabolism ...................................... 771
*Mushrooms*, adulteration, U.S.D.A .................................. 863
  as a substitute for meat, U.S.D.A .................................. 567
  basic extractives of .................................................. 567
  poisonous, immunization against ................................... 683
*Muskmelon* diseases, notes, Conn. State (See U.S.D.A.) ....... 545
  treatment, Va. Truck .................................................. 136
*Muskmelons*, analyses .................................................. 372
  culture, Ark ............................................................. 136
  in Guan, U.S.D.A .................................................... 837
  insects affecting, N.C ................................................ 700
Muskrats, studies and bibliography, U.S.D.A ......................... 248
Mustard—
  fertilizer experiments ................................................ 631
  for poultry ............................................................... 875
  seed meal, analyses, N.J .............................................. 774
  substitute for, U.S.D.A ............................................. 467
  utilization of ammonium salts by .................................. 225
  white, analyses ........................................................ 272
  wild, destruction ...................................................... 230
  Can .......................................................... 527
  host of cabbage aphids, N.Y.Cornell ................................ 658
  labeling, U.S.D.A .................................................... 467
  yield as affected by manganese ...................................... 731
Mutation theory, treatise .............................................. 29
Mutton, sources of world's supplies .................................. 675
Mycological survey, notes, N.Dak ..................................... 650
Mycetum theory, studies ................................................ 228
*Mycenae* civitella*, notes ............................................. 250
*Myiopsis dermatotax*, relation to ox warble flies ................. 56
*Myopites lumbardii*, notes ........................................... 558
*Myriae halipennis*, manufacture of wax from ....................... 416
Myronate of potassium, absorption by plants ....................... 433
*Mysticus spp.*, notes .................................................. 852
*Mystilus fasciata* n. sp., description ............................ 852
spp., notes .............................................................. 251
*Mystilus edulis*, utilization ........................................ 163

Page.

*Mycus persicus*. (See Peach aphid, green.) ......................... 250
  *M. niger*. (See Peach aphid, black.) ........................... 250
Narcissus fly, notes ................................................... 250
Narcotics, treatise ..................................................... 862
Narras, analyses ....................................................... 62
*Nasonia* torriciei n. sp., description .............................. 58
National congress of farmers .......................................... 800
Dalry Show at Chicago ................................................ 799
Educational Association, proceedings ................................ 791
Forest Administrative Act ............................................. 748
  U.S.D.A .................................................. 647
  forests, cutting and regeneration ................................ 842
Soil Fertility League, notes .......................................... 700
Natural resources, conservation, handbook ........................... 190
Nature study, course in .............................................. 496
  in agricultural schools ............................................. 792
  Ceylon ......................................................... 193
  high schools ...................................................... 98
  rural schools ...................................................... 393
  relation to agriculture ............................................ 694
  textbook ........................................................... 898
*Navae puchii*, notes .................................................. 401
Naval stores, production in United States ......................... 240
  relation of light chipping to yield, U.S.D.A. ................ 647
*Necaxarta spinigera*, injurious to bananas ......................... 452
Nebraska Station, financial statement ................................ 889
  notes .......................................................... 499,900
  report .......................................................... 690
University, notes ..................................................... 499,868
*Nectarophora pisi*, notes ............................................ 53
*Nectria cinacarina*, notes, N.Y. State (See Nectria cinacarina) 848
  *N. ditissima*, treatment .......................................... 655
Nematode eggs and larvae, viability ................................ 151
Nematodes, injurious to bananas ..................................... 452
  horses ......................................................... 688
  ruminants, U.S.D.A ............................................. 387
  sugar cane ....................................................... 847
  new species, descriptions ........................................ 783
  of Australia ....................................................... 461
*Nematodirus filicollis*, viability .................................. 151
*Nematous criccorini*, notes ........................................ 230,357
  parasitism ....................................................... 58
*Neocellia stephenla*, malarial infection of ....................... 239
*Neoclytus caprae*, notes, U.S.D.A ................................ 558
  *N. erythrocephalus*, notes, U.S.D.A .......................... 559
*Neocosmospora hastinca* as affected by tarnin .................... 524
  studies .......................................................... 44
  N.C .......................................................... 244
Nephelium, fertilizing value ......................................... 727
*Nephelium littiha*, notes, Hawaii .................................. 337
Nettle, destruction, Hawaii ........................................... 37
Neuritis, multiple, in fowls, studies ................................ 805
*Neuroterus lenticularis*, studies .................................. 301
Nevada Station, financial statement ................................ 899
  report of director ............................................. 899
New Hampshire College, notes ....................................... 397
  *N. 499,697,797
  Station, financial statement .................................... 394
  notes .......................................................... 397,499,797
  report of director ............................................. 394
Jersey College, notes ................................................ 499
EXPERIMENT STATION RECORD.

Nitrate assimilation by plants. 435
Nitrites, detection in water. 410
determination, N.C. 810
Nitrogen—
amid, determination in proteins 613
amino, determination. 710
and sulphur, relationship in metabolism. 572
assimilation in green leaves, studies 223
atmospheric—
assimilation by fungi 228
plant trichomes 326
plants 633
fixation... 23, 24
and oxidation 517
utilization. 217, 629
availability in fertilizers 204
available organic, determination. 612
balance in rice diet 767
compounds of alfalfa, Nev. 810
organic, absorption by plants 433
content of rain and snow... 509, 612
soils, variations, Pa. 830
sugar beets 443
cycle, chemistry of... 226
of plant, determination. 200, 322, 612, 709
in organic substances 108
Kjeldahl method... 10
distribution in carnations 325
fertilizing value 541
Tex. 628
fixation, bibliography 629
by Azotobacter 422
in soils 122, 227
Colo 814, 815
studies, Va. 816
gain in animals, studies 674
gathering plants, studies, U.S.D.A. 527
in ox blood and serum, solubility 179
insoluble, availability in fertilizers 826
lime. (See Calcium cyanamid.)
loss from manure... 427, 517, 826
manufacture from the air 517
nitrate, determination 804
nonproteid, relation to organic phosphorus in seeds... 432
organic chemistry of, treatise 201
in peat soils, Mich 623
soils, studies 623
Iowa 622
Pa. 821
partition as affected by fasting 267
in feces 167
supply of soils, relation to soil climate 823
use in Tennessee soils 518
Nitrogenous—
constituents in milk and cream, relationship 311
of muscles, distribution 67
extracts of veal and beef, comparison 167
fertilizers—
comparison... 216, 628, 629
effect on sugar content of cane... 733
hygroscopicity 727
injurious to citrus fruits, Fla. 457
manufacture from peat 22
substances, solution of, importance in
distillation... 115

Nitrate of soda—
deposits in Texas... 29
effect on—
digestion of soluble starch 365
flintiness of wheat 331
flow of latex... 240
nitrate formation in soils, N.J. 423
soils 514
effects of continuous use, Pa. 820
fertilizing value... 33, 133, 217, 322, 428, 510, 518, 628
Alaska 825
Ga 233
Hawaii 328
N.H 331
N.J 445
Pa 832
hygroscopicity 727
industry of Chile 322
penetration of soils by... 120
production and use in 1910... 23, 122
residual effects, Va... 735
use in mixed fertilizers 120
Nitrate reduction, rôle of bacteria in... 526
Nitrate—
assimilation by wheat seedlings, U.S.D.A. 321
determination, N.C. 810
in milk. 14
in water... 410, 613
formation in soils... 514, 326, 622
N.J. 423
in air of southern regions 17
movement in clay soils... 116
soil, effect on trees, Colo... 814
solubility in soils, N.C. 810
Nitrate—
determination... 106, 804
N.C. 804
in vegetable products 715
formation in living cells... 633
manufacture from the air... 217
Nitric acid—
determination... 106, 804
N.C. 804
in vegetable products 715
formation in living cells... 633
manufacture from the air... 217
Nitrification—
as affected by fertilizers, Pa... 820
by ultraviolet rays... 629
in soils... 227, 514
Hawaii... 824
and solutions, N.C. 816

New Jersey Stations, financial statement... 487
notes... 97, 300, 397-499
report of director... 497
Mexico College, notes... 797
Station, financial statement... 299
notes... 797
report of director... 299
York Cornell Station, notes... 697, 900
State Station, notes... 307, 697
Nico-fume, insecticidal value, N.Y. Cornell... 659
Nicotin, determination in—
concentrated tobacco juices... 211, 212
insecticides, U.S.D.A. 16
Night soil, fertilizing value... 214
utilization... 213
Nitragin, tests... 128, 540
Nitro-nitrate, fertilizing value... 518
Nitrogen assimilation by plants... 455
industry in Norway... 518
Norwegian. (See Calcium nitrate.)
of lime. (See Calcium nitrate.)

Nitrogen—
constituents in milk and cream, relationship 311
of muscles, distribution 67
extracts of veal and beef, comparison 167
fertilizers—
comparison... 216, 628, 629
effect on sugar content of cane... 733
hygroscopicity 727
injurious to citrus fruits, Fla. 457
manufacture from peat 22
substances, solution of, importance in
distillation... 115

Nitric acid—
determination... 106, 804
N.C. 804
in vegetable products 715
formation in living cells... 633
manufacture from the air... 217
Nitrification—
as affected by fertilizers, Pa... 820
by ultraviolet rays... 629
in soils... 227, 514
Hawaii... 824
and solutions, N.C. 816

New Jersey Stations, financial statement... 487
notes... 97, 300, 397-499
report of director... 497
Mexico College, notes... 797
Station, financial statement... 299
notes... 797
report of director... 299
York Cornell Station, notes... 697, 900
State Station, notes... 307, 697
Nico-fume, insecticidal value, N.Y. Cornell... 659
Nicotin, determination in—
concentrated tobacco juices... 211, 212
insecticides, U.S.D.A. 16
Night soil, fertilizing value... 214
utilization... 213
Nitragin, tests... 128, 540
Nitro-nitrate, fertilizing value... 518
Nitrogen assimilation by plants... 455
industry in Norway... 518
Norwegian. (See Calcium nitrate.)
of lime. (See Calcium nitrate.)

Nitrogen—
constituents in milk and cream, relationship 311
of muscles, distribution 67
extracts of veal and beef, comparison 167
fertilizers—
comparison... 216, 628, 629
effect on sugar content of cane... 733
hygroscopicity 727
injurious to citrus fruits, Fla. 457
manufacture from peat 22
substances, solution of, importance in
distillation... 115

Nitric acid—
determination... 106, 804
N.C. 804
in vegetable products 715
formation in living cells... 633
manufacture from the air... 217
Nitrification—
as affected by fertilizers, Pa... 820
by ultraviolet rays... 629
in soils... 227, 514
Hawaii... 824
and solutions, N.C. 816

INDEX OF SUBJECTS.

Page. Refractometer, Immersion, water bath for, U.S.D.A. 311
Refrigeration, artificial, experiments 65
Refrigerator, homemade, description 394
Rennet, cleavage of proteins by 202
conglutination of milk by 13
Reptiles, treatise 50
Resin and mineral oil, methods of analysis 414
Respiration apparatus for small animals 471
paper on 471
calorimeter at Berlin Agricultural College 173
construction and operation, U.S.D.A. 570
description 867
experiments with fruit, U.S.D.A. 729
plants 729
in plants, studies 124
Respiratory—exchange as affected by body position 270
in man, apparatus for determining 570
relation to surface area 68
quotient as affected by preceding diet 267
Reticilia frustrana, studies 855
Rhombocnemis (Sphacnemis) obesarius, studies, U.S.D.A. 665
Ragoletis cerasi, notes 250
pomonella. (See Apple maggot.)
Rhamnus spp., studies, U.S.D.A. 651
Rheumatic cure, misbranding, U.S.D.A. 769
Rhipicephalus appendiculatus, relation to amakebe 882
decolaris, notes 586
cervisii, relation to anaplasmosis in donkeys 183
sp., fumigation experiments 887
Rhizoctonia medicaginis, occurrence in America 547
sp., notes, Can. 548
spp. as affected by tannin 524
violacea, notes 246
Rhizoglypha haeumichi (echniopus), notes 664
Rhizopertha dominica, studies, U.S.D.A. 663
Rhizopus nigricans, studies, La. 350
Rhodes Island College, notes 698
Station, financial statement 394
notes 398, 698
report of director 394
Rhodesian redwater. (See African coast fever.)
Rhopalocystis nigra, description 546
Rhubarb, forcing experiments 536
occurrence of allantoin in 168
Rhynchosporum palmarum, notes 254, 555
phascis, notes 251
Ribes aureum, fungus disease affecting 849
Rice, adulteration and misbranding, U.S.D.A. 769
analyses 767
army worm, notes 357
as a foodstuff 767
bran, protective power in rice diet 866
use against beriberi 179
by-products, analyses, La. 477
culture in India 391

Page. 985

Raphanus raphanistrum, host of cabbage aphid, N.Y. Cornell 658
sativus, nitrogen assimilation by 633
Raspberries—
Armillaria mellea affecting 348
culture, Alaska 836
destruction by sage thrasher 150
frost injuries to 847
fungus disease affecting 849
insects affecting 357
Mich 137
new, descriptions, U.S.D.A. 540
red, host of orange thrips, U.S.D.A. 657
ripening processes of 262
Raspberry—
cane blight, notes, N.Y. State 244
diseases, treatment, Colo. 540
Mich 137
fruit sirup, adulteration and misbranding, U.S.D.A. 468
industry in Colorado, Colo. 540
Rat fleas affecting man 702
development of Trypanosoma lewisi in 852
leprosy, studies and bibliography 249
plague cultures, tests 881
Rations, campaign, for soldiers, emergency, suggestions for 369
Rats, destruction by hydrocyanic-acid gas 363
extermination 541
feeding experiments 864
injurious to sugar cane, U.S.D.A. 665
marginal points in 183
metabolism experiments 168, 676
relation to bubonic plague 554
transplanting of testicles in 867
white, excision of seminal organs 574
feeding experiments 676
wood, host of spotted fever tick, U.S.D.A. 756
Rectal prolapse in a hog, treatment 291
Recurrent fever, prevalence in Colombia 556
treatment 553
Red clover. (See Clover, red.)
dog flour. (See Flour, red dog.)
gum, culture in Texas 343
spider. (See Spider, red.)
Redtop, analyses, Ohio 437
Wyoming 130
notes, Ohio 437
seed, adulteration and misbranding, U.S.D.A. 237
Reductase, physiology of 123, 411
relation to catalase 609
Reductases of cow's milk, studies 202
Redwater—
ocurrence in British Columbia 880
Rhodesian. (See African coast fever.) (See also Texas fever.)
Reforestation—
in Massachusetts 242
North Carolina 140
prairie States 747
of Douglas fir lands, U.S.D.A. 141
relation to seed-eating mammals, U.S.D.A. 49

### Experimental Station Record

#### Vegetables—Continued.
- Culture under frames, U.S.D.A. ............................................. 741
- Fertilizer experiments .......................................................... 237, 642
- For Colorado ................................................................. 537
- Insects affecting ............................................................... 290, 852
- U.S.D.A ................................................................. 642
- Wash ................................................................. 540
- Occurrence of allantoic in .................................................. 168
- Raw and cooked, digestibility .............................................. 264
- Treatise ................................................................. 336
- Varieties ................................................................. 642
- P.R. ................................................................. 741
- For Ontario, Canada ....................................................... 537
- Oregon ................................................................. 237

(See also specific kinds.)

#### Vegetation—
- As affected by atmospheric impurities .................................. 813
- Freezing ................................................................. 128
- Frost ................................................................. 28
- Of central Utah, notes ...................................................... 619
- Velvet beans, culture, Fla .................................................. 435
- Experiments, Hawaii ......................................................... 734
- In Guam, U.S.D.A. ......................................................... 830
- For dairy cows, Fla ........................................................ 474
- Hybridization experiments, Fla ........................................... 436
- Notes, U.S.D.A. .......................................................... 394
- Tests, Fla ............................................................... 435
- Leaf, notes, N.J. .......................................................... 445

#### Ventilation, Studies ...................................................... 165
- Venturia sacchari, notes ..................................................... 847
- Veronica carolyni, parasite on citrus white fly ................................ 661
- Vermicularia dissertata n.sp., notes ..................................... 650
- Vermont Station, notes ...................................................... 98, 150, 500
- University, notes .......................................................... 98, 195, 500
- Vernix, occurrence in sugar beets .......................................... 201
- Vertebrates, cold-blooded, infection experiments .................................. 783
- Verticillium alboatrum, notes .............................................. 454
- Vespa crabro, notes, N.J. ................................................... 460

#### Vetch as affected by tobacco smoke ................................. 225
- Carolina milk, analyses, Wyo ............................................... 131
- Common, detection in coffee ............................................... 467
- Marsh, analyses, Wls. ........................................................ 173
- Notes ................................................................. 132
- Roots, fertilizing value ...................................................... 120
- Seed, analyses .............................................................. 272
- Winter, culture, Mich ........................................................ 743
- Yield as affected by source of seed, Can .................................. 529

#### Veterinary Instruction in the Philippines ....................... 196
- Medicine, discussion ........................................................ 466
- Parasitology, treatise ....................................................... 175
- Vicia faba, formation of chromogens in ................................ 121
- Use in anaphylaxis ............................................................ 283
- Spp., analyses .............................................................. 272

#### Viellia, biological reactions of ........................................ 9
- Vienna Institution for Experimental Biology .......................... 472
- Vignin, biological reactions of ............................................. 9
- Vine disease, California, studies .......................................... 147
- Weevi7, black, notes, Me .................................................. 555

#### Vinegar—Continued.
- Adulteration, U.S.D.A. ....................................................... 368, 468, 669, 769, 863
- Detection ................................................................. 206
- Cereal, manufacture .......................................................... 115
- Determination of solids in ................................................ 12

### Water—
- Absorbing power of desert plants ........................................ 430
- Acid, effect on vegetation ............................................... 434
- Adulteration and misbranding, U.S.D.A. ................................ 468
- Analyses ............................................................... 105, 115, 510, 619
- Geochemical interpretation .............................................. 813
- Industrial use ............................................................ 813
- Bacteriology of .......................................................... 422
- Balance of succulent plants ............................................. 219
- Bath for immersion refractometer, description, U.S.D.A. .............. 311
- Biological properties ..................................................... 618
- Chemistry of ............................................................. 618
- Circulation in cultivated soils ......................................... 116
- Content of seeds, effect on germination ................................ 431
- Soils at different depths ................................................ 621
- Decomposition by ultraviolet rays ...................................... 510
- Determination in butter ................................................... 413
- U.S.D.A ............................................................... 308
- Pa ................................................................. 108
- Foods ................................................................. 621
- Soils ................................................................. 209, 412
- Sugar ................................................................. 410
- Various substances ....................................................... 116
- Disinfection, bibliography ................................................ 213
- Drinking with meals, effect .............................................. 268, 572
- Duty of ................................................................. 635
- U.S.D.A ............................................................... 489, 309
- Effect on gastric secretion ................................................ 66
